(AFFILIATED TO MANONMANIAM SUNDARANAR UNIVERSITY, TIRUNELVELI)

DEPARTMENT OF MATHEMATICS

CLASS : II B.SC (MATHEMATICS)  
SUBJECT : REAL ANALYSIS – I ( SMMA31)

SEM: III

4

**SEMESTER – III**

**CORE PAPER –V**  
**REAL ANALYSIS - I (90 Hours) (SMMA31)**

L T P C
2 4 0 4

Objectives:

- To lay a good foundation of classical analysis
- To study the behaviour of sequences and series

**Unit I Real number system :**

The field of axioms, the order axioms, the rational numbers, the irrational numbers, upper bounds, maximum element, least upper bound (supremum). The completeness axiom, absolute values, the triangle inequality. Cauchy – schwartz's inequality. **11L**

**Unit II Sequences :** Bounded sequences – monotonic sequences – convergent sequences – divergent and oscillating sequences – The algebra of limits. **17L**

**Unit III** Behaviour of monotonic sequences – Cauchy's first limit theorem – Cauchy's second limit theorem – Cesaro's theorem – subsequences - Cauchy sequence – Cauchy's general principle of convergence. **19L**

**Unit IV Series :** Infinite series –  $n^{\text{th}}$  term test – Comparison test – Kummer's test – D'Alembert's ratio test – Raabe's test - Gauss test – Root test **23L**

**Unit V** Alternating series – Leibnitz's test - Tests for convergence of series of arbitrary terms – Multiplication of series- Abel's Theorem-Mertens theorem-Power Series-Radius of convergence **20L**

**Text Books:**

- Arumugam .S and Thengapandi Issac – “sequences and series”, New Gamma publishing House, Palayamkottai – 627 002.
- Tom M. Apostol – Mathematical Analysis, II Edition, Narosa Publishing House, New Delhi (unit I)

**Book for Reference :**

- Goldberg .R – Methods of Real Analysis, Oxford and IBH Publishing Co., New Delhi.

## REAL NUMBER SYSTEM

### Field Axioms

**Axiom 1:**  $x + y = y + x$ ,  $xy = yx$  (Commutative law)

**Axiom 2:**  $x + (y + z) = (x + y) + z$ ,  $x(yz) = (xy)z$  (Associative law)

**Axiom 3:**  $x(y + z) = xy + xz$  (Distributive law)

**Axiom 4:** Given any two real number  $x$  and  $y$  there exists a real number  $z$  such that

$$x + z = y \dots(1)$$

$$z = y - x$$

$$x + (y - x) = y$$

$$(x - x) + y = y$$

$$x - x = 0$$

Therefore  $x$  is a negative of  $x$ .

**Axiom 5:** There exists atleast one real number  $x \neq 0$ . If  $x$  and  $y$  are two real numbers with  $x \neq 0$ . There exists a real number  $z$  such that  $xz = y$  implies  $z = \frac{y}{x}$ .

$$x \left(\frac{y}{x}\right) = y$$

$$\left(\frac{x}{x}\right) y = y$$

$$\Rightarrow \left(\frac{x}{x}\right) y = 1 \cdot y$$

$$\Rightarrow x x^{-1} = 1 \frac{y}{x}$$

$$\Rightarrow x^{-1} = \frac{1}{x}, x \neq 0.$$

$\frac{1}{x}$  is the inverse of  $x$ .

$x^{-1}$  is the reciprocal of  $x$ .

## Order Axioms

The existence of a relation  $<$  which establishes an ordering among the real numbers and which satisfy the following axioms.

Axiom 6: Exactly one of the relations  $x = y$ ,  $x < y$ ,  $x > y$  holds.

Axiom 7: If  $x < y$ , then for all  $z$ , we have  $x + z < y + z$ .

Axiom 8: If  $x > 0$  and  $y > 0$  then  $xy > 0$

Axiom 9: If  $x > y$  and  $y > z$  then  $x > z$

## Rational Numbers

$$Q = \left\{ \frac{a}{b} \mid a \text{ and } b \text{ are integers } b \neq 0 \right\}$$

### Example

1. If  $a$  and  $b$  are rational numbers, then  $\frac{a+b}{2}$  is also a rational number.
2. Between any two rational numbers, there are infinitely many rational numbers.
3. The field axiom and order axioms are satisfied by  $Q$ .

## Irrational Numbers

Real numbers which are not rational are called irrational numbers

Theorem 1.1 : Given real numbers  $a$  and  $b$  such that  $a \leq b + \epsilon$  for all  $\epsilon > 0$ . Then  $a \leq b$ .

Proof: We have to prove this theorem by contradiction method. Suppose  $a > b$ .

Given  $a, b \in \mathbb{R}$ ,  $a \leq b + \epsilon$ , for all  $\epsilon > 0$ . Take  $\epsilon = \frac{a-b}{2}$ .

Then  $b + \epsilon = \frac{a-b}{2} + b$ .

$$b + \epsilon = \frac{a-b+2b}{2}$$

$$b + \epsilon < a.$$

But given  $b + \epsilon \geq a$ , which is a contradiction.

Therefore our assumption is wrong.

Thus  $a \leq b$ .

**Definition :**

A subset A of R is said to be **bounded above** if there exists an element  $\alpha \in R$  such that  **$a \leq \alpha$  for all  $a \in A$ .**

$\alpha$  is called an **upper bound** of A.

**Definition :**

A subset A of R is said to be **bounded below** if there exists an element  $\beta \in R$  such that  **$a \geq \beta$  for all  $a \in A$ .**

$\beta$  is called a **lower bound** of A.

**Definition :**

A is said to be **bounded** if it is both bounded above and bounded below.

**Least Upper Bound and Greatest Lower Bound:**

**Definition :**

Let A be a subset of R and  **$u \in R$** . u is called **the least upper bound or supremum** of A if i) u is an upper bound of A.  
ii)  **$v < u$**  then v is not an upper bound of A.

**Definition :**

Let A be a subset of R and  $l \in R$ . l is called **the greatest lower bound or infimum** of A if i) l is a lower bound of A.  
if  **$m < l$**  then m is not a lower bound of A.

**Examples:**

1. Let  $A = \{1, 3, 5, 6\}$ . Then glb of A = 1 and lub of A = 6
2. Let  $A = (0,1)$ . Then glb of A = 0 and lub of A = 1. In this case both glb and lub do not belong to A.

**Bounded Functions:**

**Definition:**

Let  **$f : A \rightarrow R$**  be any function. Then the range of f is a subset of R. f is said to be **bounded function** if its range is a bounded subset of R.

**Remark :**

f is a bounded function iff there exists a real number m such that  **$|f(x)| \leq m$  for all  $x \in R$ .**

1.  $f : [0,1] \rightarrow \mathbb{R}$  given by  $f(x) = x + 2$  is a bounded function where as  $f : \mathbb{R} \rightarrow \mathbb{R}$  given by  $f(x) = x + 2$  is not a bounded function.
2.  $f : \mathbb{R} \rightarrow \mathbb{R}$  defined by  $f(x) = \sin x$  is a bounded function. Since  $|\sin x| \leq 1$ .

**Absolute Value:**

**Definition:** For any real number  $x$  we defined the **modulus** or the **absolute value** of  $x$  denoted by  $|x|$  as follows  $|x| = \begin{cases} x & \text{if } x > 0 \\ -x & \text{if } x \leq 0 \end{cases}$ .

Clearly  $|x| \geq 0$  for all  $x \in \mathbb{R}$ .

**Triangle inequality**

For arbitrary real  $x$  and  $y$  we have  $|x + y| \leq |x| + |y|$

**Proof:**

We know that  $-|x| \leq x \leq |x| \longrightarrow (1)$

and  $-|y| \leq y \leq |y| \longrightarrow (2)$

(1)+(2) =>  $-[|x| + |y|] \leq x + y \leq |x| + |y|$ .

By theorem, " If  $a \geq 0$ , then we have the inequality  $|x| \leq a$  iff  $-a \leq x \leq a$  " .

Hence,  $|x + y| \leq |x| + |y|$ .

**Cauchy-schwarz inequality**

**Theorem:1.1** If  $a_1, \dots, a_n$  and  $b_1, \dots, b_n$  are real numbers, then

$$(\sum_{i=1}^n a_i b_i)^2 \leq \sum_{i=1}^n a_i^2 \sum_{i=1}^n b_i^2 \dots\dots\dots(1)$$

Or, equivalently

$$|\sum_{i=1}^n a_i b_i| \leq \sqrt{\sum_{i=1}^n a_i^2} \sqrt{\sum_{i=1}^n b_i^2} \dots\dots\dots(2)$$

We will use mathematical induction as a method for the proof. First we observe that

$$(a_1b_2 - a_2b_1)^2 \geq 0$$

By expanding the square we get

$$(a_1b_2)^2 + (a_2b_1)^2 - 2a_1b_2a_2b_1 \geq 0$$

After rearranging it further and completing the square on the left-hand side, we get

$$a_1^2b_1^2 + 2a_1b_1a_2b_2 + a_2^2b_2^2 \leq a_1^2b_1^2 + a_1^2b_2^2 + a_2^2b_1^2 + a_2^2b_2^2$$

By taking the square roots of both sides, we reach

$$|a_1b_1 + a_2b_2| \leq \sqrt{a_1^2 + a_2^2} \sqrt{b_1^2 + b_2^2} \dots\dots\dots(3)$$

which proves the inequality (2) for n = 2.

Assume that inequality (2) is true for any n terms. For n + 1, we have that

$$\sqrt{\sum_{i=1}^n a_i^2} \sqrt{\sum_{i=1}^n b_i^2} = \sqrt{\sum_{i=1}^n a_i^2 + a_{n+1}^2} \sqrt{\sum_{i=1}^n b_i^2 + b_{n+1}^2} \dots\dots\dots(4)$$

By comparing the right-hand side of equation (4) with the right-hand side of inequality (3)

we know that

$$\sqrt{\sum_{i=1}^n a_i^2 + a_{n+1}^2} \sqrt{\sum_{i=1}^n b_i^2 + b_{n+1}^2} \geq \sqrt{\sum_{i=1}^n a_i^2} \sqrt{\sum_{i=1}^n b_i^2} + |a_{n+1}b_{n+1}|$$

Since we assume that inequality (2) is true for n terms, we have that

$$\begin{aligned} &\sqrt{\sum_{i=1}^n a_i^2} \sqrt{\sum_{i=1}^n b_i^2} + |a_{n+1}b_{n+1}| \geq \sum_{i=1}^n a_i b_i + |a_{n+1}b_{n+1}| \\ &\geq \sum_{i=1}^n a_i b_i \end{aligned}$$

which proves the C-S inequality.

**Theorem:1.2**

Given real numbers a and b such that  $a \leq b + \epsilon$  for every  $\epsilon > 0$  . Then  $a \leq b$

**Proof:**

Given  $a \leq b + \epsilon$  for every  $\epsilon > 0$  .....(1)

Suppose  $b < a$

Choose  $\epsilon = a - b / 2$

Now,  $b + \epsilon = b + a - b / 2$

$$\begin{aligned} &= (2b + a - b) / 2 \\ &= (a + b) / 2 < (a + a) / 2 \\ &= 2a / 2 = a \end{aligned}$$

Therefore,  $b + \varepsilon < a$  which is a contradiction to (1)  
Hence  $a \leq b$

**Theorem: 1.3**

If  $n$  is positive integer which is not a perfect square, then  $\sqrt{n}$  is irrational.

**Proof:**

Let  $n$  contains no square factor  $> 1$

Suppose  $\sqrt{n}$  is rational

Then  $\sqrt{n} = a/b$ , where  $a$  and  $b$  are integers having no factor in common.

$$\text{implies } n = \frac{a^2}{b^2}$$

$$\Rightarrow b^2 n = a^2 \dots\dots(1)$$

But  $b^2 n$  is a multiple of  $n$ , so  $a^2$  is also a multiple of  $n$

However if  $a^2$  is a multiple of  $n$ ,  $a$  itself must be a multiple of  $n$ . (since  $n$  has no square factor  $> 1$ )

$$\Rightarrow a = cn, \text{ where } c \text{ is an integer}$$

sub in (1)

$$b^2 n = c^2 n^2$$

$$b^2 = nc^2$$

Therefore  $b$  is a multiple of  $n$ , which is a contradiction to  $a$  and  $b$  have no factor in common.

Hence  $\sqrt{n}$  is irrational

If  $n$  has a square factor, then  $n = m^2 k$ , where  $k > 1$  and  $k$  has no square factor  $> 1$ .

$$\text{Then } \sqrt{n} = m\sqrt{k}$$

If  $\sqrt{n}$  is rational, then the numbers  $\sqrt{k}$  is also rational. Which is a contradiction to  $k$  is no square factor  $> 1$ . Hence  $n$  has no square factor.

**Problem:**

Prove that  $\sqrt{2}$  is irrational.

**Theorem :** If  $e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \frac{x^4}{4!} + \dots + \frac{x^n}{n!} + \dots$ , then e is irrational.

Proof: Let  $x = 1$ . Then  $e^1 = 1 + 1 + \frac{1^2}{2!} + \frac{1^3}{3!} + \frac{1^4}{4!} + \dots$

and let  $x = -1$ . Then  $e^{-1} = 1 - 1 + \frac{1}{2!} - \frac{1}{3!} + \frac{1}{4!} - \dots$

$$S_n = \sum_{k=0}^n \frac{(-1)^k}{k!} \text{ then } S_{2k-1} = \sum_{k=0}^{2k-1} \frac{(-1)^{2k-1}}{(2k-1)!}$$

$$e^{-1} - S_{2k-1} = \frac{1}{2!} + \frac{1}{4!} + \frac{1}{6!} + \dots$$

$$0 < e^{-1} - S_{2k-1} < \frac{1}{(2k)!}$$

$$0 < e^{-1} - S_{2k-1} < \frac{1}{(2k-1)!2k}$$

$$0 < (2k - 1)! (e^{-1} - S_{2k-1}) = \frac{1}{2k} \leq \frac{1}{2} \text{ for any integer } k \geq 1.$$

Since  $(2k - 1)!$  Is an integer,  $(2k - 1)! (e^{-1} - S_{2k-1})$  is always an integer.

$$0 < (2k - 1)! (e^{-1} - S_{2k-1}) = \frac{1}{2k} \leq \frac{1}{2}$$

If  $e^{-1}$  is rational,  $(2k - 1)! e^{-1}$  is an integer, which would lie between 0 and  $\frac{1}{2}$ .

Which is a contradiction.

Hence, e cannot be rational.

## UNIT - II SEQUENCES

**Definition.** Let  $f : \mathbb{N} \rightarrow \mathbb{R}$  be a function and let  $f(n) = a_n$ . Then  $a_1, a_2, \dots, a_n$  is called the sequences in  $\mathbb{R}$  determined by the function  $f$  and is denoted by  $(a_n)$ .

$a_n$  is called the  $n^{\text{th}}$  term of the sequence. The range of the function  $f$  which is a subset of  $\mathbb{R}$ , is called the range of the sequence

### Examples.

- a) The function  $f : \mathbb{N} \rightarrow \mathbb{R}$  given by  $f(n) = n$  determines the sequence  $1, 2, 3, \dots, n$ ,
- b) The function  $f : \mathbb{N} \rightarrow \mathbb{R}$  given by  $f(n) = n^2$  determines the sequence  $1, 4, 9, \dots, n^2, \dots$

### **Definition:**

A sequence  $(a_n)$  is said to be **bounded above** if there exists a real number  $k$  such that  $a_n \leq k$  for all  $n \in \mathbb{N}$ .  $k$  is called an upper bound of the sequence  $(a_n)$ .

A sequence  $(a_n)$  is said to be **bounded below** if there exists a real number  $k$  such that  $a_n \geq k$  for all  $n$ .  $k$  is called a **lower bound** of the sequence  $(a_n)$ .

A sequence  $(a_n)$  is said to be a **bounded sequence** if it is both bounded above and below.

### Note.

A sequence  $(a_n)$  is bounded if there exists a real number  $k > 0$  such that  $|a_n| < k$  for all  $n$

### Examples.

1. Consider the sequence  $1, 1/2, 1/3, \dots, 1/n, \dots$ . Here  $1$  is the l.u.b and  $0$  is the g.l.b. It is a bounded sequence.
2. The sequence  $1, 2, 3, \dots, n, \dots$  is bounded below but not bounded above.  $1$  is the g.l.b of the sequence.
3. The sequence  $-1, -2, -3, \dots, -n, \dots$  is bounded above but not bounded below.  $-1$  is the l.u.b of the sequence.
4.  $1, -1, 1, -1, \dots$  is a bounded sequence.  $1$  is the l. u. b  $-1$  is the g. l. b of the sequence
5. Any constant sequence is a bounded sequence. Here l.u.b = g. l. b = the constant term of the sequence.

### Monotonic sequence

**Definition:** A sequence  $(a_n)$  is said to be monotonic increasing if  $a_n \leq a_{n+1}$  for all  $n$ .  $(a_n)$  is said to be monotonic decreasing if  $a_n \geq a_{n+1}$  for all  $n$ .  $(a_n)$  is said to be strictly monotonic decreasing if  $a_n < a_{n+1}$  for all  $n$ .  $(a_n)$  is said to be monotonic if it is either monotonic increasing or monotonic decreasing.

### Example.

1.  $1, 2, 2, 3, 3, 3, 4, 4, 4, 4, \dots$  is a monotonic increasing sequence.
2.  $1, 2, 3, 4, \dots$  is a strictly monotonic increasing sequence
3. The sequence  $(a_n)$  given by  $1, -1, 1, -1, 1, \dots$  is neither monotonic increasing nor monotonic decreasing. Hence  $(a_n)$  is not a monotonic sequence.
4.  $\left(\frac{2n-7}{3n+2}\right)$  is a monotonic increasing sequence.

**Proof:**

$$a_n - a_{n+1} = \frac{2n-7}{3n+2} - \frac{2(n+1)-7}{3(n+1)+2}$$

$$= \frac{-25}{(3n+2)(3n+5)} < 0$$

Therefore  $a_n < a_{n+1}$

Hence the sequence is monotonic increasing.

5. Consider the sequence  $(a_n)$  where  $a_n = 1 + \frac{1}{1!} + \frac{1}{2!} + \dots + \frac{1}{n!}$ . Clearly  $(a_n)$  is a monotonic increasing sequence.

**Note:** A monotonic increasing sequence  $(a_n)$  is bounded below and  $q_1$  is the g.l.b of the sequence.

A monotonic decreasing sequence  $(a_n)$  is bounded above and  $a_1$  is l. u. b of the sequence.

**Solved Problems:**

Show that if  $(a_n)$  is a monotonic sequence then  $(\frac{a_1+a_2+\dots+a_n}{n})$  is also a monotonic sequence.

**Solution:**

Let  $(a_n)$  be a monotonic increasing sequence.

Therefore  $a_1 \leq a_2 \leq a_3 \leq \dots \dots \leq a_n \leq \dots \dots \dots (1)$

Let  $b_n = (\frac{a_1+a_2+\dots+a_n}{n})$

Now,  $b_{n+1} - b_n = \frac{a_1+a_2+\dots+a_{n+1}}{n+1} - \frac{a_1+a_2+\dots+a_n}{n}$

$$\geq \frac{na_{n+1} - (a_1 + a_2 + \dots + a_n)}{n(n+1)}$$

$$= \frac{na_{n+1} - (a_n + a_n + \dots + a_n)}{n(n+1)} \quad \text{by (1)}$$

$$= \frac{n(a_{n+1} - a_n)}{n(n+1)}$$

$$\geq 0$$

Therefore,  $b_{n+1} \geq b_n$ .

Therefore  $(b_n)$  is monotonic increasing.

The proof is similar if  $(a_n)$  is monotonic decreasing.

**Convergent sequences**

**Definition.** A sequence  $(a_n)$  is said to converge to a number  $l$  if given  $\epsilon > 0$  there exists a positive

integer  $m$  such that  $a_n - l < \epsilon$  for all  $n \geq m$ . We say that  $l$  is the limit of the sequence and we write

$$\lim_{n \rightarrow \infty} a_n = l \text{ or } (a_n) \rightarrow l$$

**Note.1**  $(a_n) \rightarrow l$  iff given  $\epsilon > 0$  there exists a natural number  $m$  such that  $a_n \in (l - \epsilon, l + \epsilon, )$  for all  $n \geq m$  i.e, All but a finite number of terms of the sequence lie within the interval  $(l - \epsilon, l + \epsilon)$ .

**Theorem. 2.1**

A sequence cannot converge to two different limits.

**Proof.** Let  $(a_n)$  be a convergent sequence.

If possible let  $l_1$  and  $l_2$  be two distinct limits of  $(a_n)$ .

Let  $\epsilon > 0$  be given.

Since  $(a_n) \rightarrow l_1$ , there exists a natural number  $n_1$

Such that  $...|a_n - l_1| < \frac{1}{2}\epsilon$  for all  $n \geq n_1$ ..... (1)

Since  $(a_n) \rightarrow l_2$ , there exists a natural number  $n_2$

Such that  $...|a_n - l_2| < \frac{1}{2}\epsilon$  for all  $n \geq n_2$ ..... (2)

Let  $m = \max \{n_1, n_2\}$

$$\text{Then } |l_1 - l_2| = |l_1 - a_m + a_m - l_2|$$

$$\leq |a_m - l_1| + |a_m - l_2|$$

$$< \frac{1}{2}\epsilon + \frac{1}{2}\epsilon \quad \text{by (1) and (2)}$$

$$= \epsilon$$

$\therefore l_1 - l_2 < \epsilon$  and this is true for every  $\epsilon > 0$ . Clearly this is possible only if  $l_1 - l_2 = 0$ .

Hence  $l_1 = l_2$

**Examples**

1.  $\lim_{n \rightarrow \infty} \frac{1}{n} = 0$

**Proof:**

Let  $\epsilon > 0$  be given.

Then  $|\frac{1}{n} - 0| = \frac{1}{n} < \epsilon$  if  $n > \frac{1}{\epsilon}$ . Hence if we choose  $m$  to any natural number

such that  $m > \frac{1}{\epsilon}$  then  $|\frac{1}{n} - 0| < \epsilon$  for all  $n \geq m$ .

$$\lim_{n \rightarrow \infty} \frac{1}{n} = 0$$

**Note.** If  $\epsilon = 1/100$ , then  $m$  can be chosen to be any natural number greater than 100. In this example the choice of  $m$  depends on the given  $\epsilon$  and  $[1/\epsilon] + 1$  is the smallest value of  $m$  that satisfies the requirements of the definition.

2. The constant sequence 1, 1, 1, ..... converges to 1.

**Proof.**

Let  $\epsilon > 0$  be given

Let the given sequence be denoted by  $(a_n)$ . Then  $a_n = 1$  for all  $n$ .

$$\therefore |a_n - 1| = |1 - 1| = 0 < \epsilon \text{ for all } n \in \mathbb{N}.$$

$$\therefore |a_n - 1| < \epsilon \text{ for all } n \geq m \text{ where } m \text{ can be chosen to be any natural number.}$$

$$\therefore \text{Lim } a_n = 1$$

$$n \rightarrow \infty$$

**Note.** In this example, the choice of  $m$  does not depend on the given  $\epsilon$

$$3. \lim_{n \rightarrow \infty} \frac{n+1}{n} = 1$$

**Proof.** Let  $\epsilon > 0$  be given.

$$\text{Now, } \left| \frac{n+1}{n} - 1 \right| = \left| 1 + \frac{1}{n} - 1 \right| = \left| \frac{1}{n} \right|$$

$\therefore$  If we choose  $m$  to be any natural number greater than  $1/\epsilon$  we have

$$\left| \frac{n+1}{n} - 1 \right| < \epsilon \text{ for all } n \geq m. \text{ Therefore, } \lim_{n \rightarrow \infty} \frac{n+1}{n} = 1$$

$$4. \lim_{n \rightarrow \infty} \frac{1}{2^n} = 0$$

**Proof.**

Let  $\epsilon > 0$  be given

$$\text{Then } \left| \frac{1}{2^n} - 0 \right| = \frac{1}{2^n} < \frac{1}{n} \quad (\text{since } 2^n > n \text{ for all } n \in \mathbb{N})$$

$$\left| \frac{1}{2^n} - 0 \right| < \epsilon \text{ for all } n \geq m \text{ where } m \text{ is any natural number greater than } 1/\epsilon$$

$$\text{Therefore, } \lim_{n \rightarrow \infty} \frac{1}{2^n} = 0$$

5. The sequence  $((-1)^n)$  is not convergent

**Proof.**

Suppose the sequence  $((-1)^n)$  converges to  $l$

Then, given  $\epsilon > 0$ , there exists a natural number  $m$  such that

$$\left| (-1)^n - l \right| < \epsilon \text{ for all } n > m.$$

$$\therefore \left| (-1)^m - (-1)^{m+1} \right| = \left| (-1)^m - l + l - (-1)^{m+1} \right|$$

$$\leq \left| (-1)^m - l \right| + \left| (-1)^{m+1} - l \right|$$

$$< \epsilon + \epsilon = 2\epsilon$$

$$\text{But } \left| (-1)^m - (-1)^{m+1} \right| = 2.$$

$$\therefore 2 < 2\epsilon$$

i.e.,  $1 < \epsilon$  which is a contradiction since  $\epsilon > 0$  is arbitrary.

$\therefore$  The sequence  $((-1)^n)$  is not convergent.

### Theorem:2.2

Any convergent sequence is a bounded sequence.

**Proof.**

Let  $(a_n)$  be a convergent sequence.

$$\text{Let } \lim_{n \rightarrow \infty} a_n = l$$

Let  $\epsilon > 0$  be given. Then there exists  $m \in \mathbb{N}$  such that  $\left| a_n - l \right| < \epsilon$  for all  $n \geq m$

$$\therefore \left| a_n \right| < \left| l \right| + \epsilon \text{ for all } n \geq m.$$

$$\text{Now, let } k = \max \{ \left| a_1 \right|, \left| a_2 \right|, \dots, \left| a_{m-1} \right|, \left| l \right| + \epsilon \}$$

Then  $|a_n| \leq k$  for all  $n$ .

$\therefore (a_n)$  is a bounded sequence.

**Note.** The converse of the above theorem is not true. For example, the sequence  $((-1)^n)$  is a bounded sequence. However it is not a convergent sequence.

### Divergent sequence

**Definition:** A sequence  $(a_n)$  is said to diverge to  $\infty$  if given any real number  $k > 0$ , there exists  $m \in \mathbb{N}$  such that  $a_n > k$  for all  $n \geq m$ . In symbols we write  $(a_n) \rightarrow \infty$  or  $\lim_{n \rightarrow \infty} a_n = \infty$

**Note.**  $(a_n) \rightarrow \infty$  if given any real number  $k > 0$  there exists  $m \in \mathbb{N}$  such that  $a_n \in (k, \infty)$  for all  $n \geq m$

### Examples

1.  $(n) \rightarrow \infty$

**Proof:** Let  $k > 0$  be any given real number.

Choose  $m$  to be any natural number such that  $m > k$

Then  $n > k$  for all  $n \geq m$ .

$\therefore (n) \rightarrow \infty$

2.  $(n^2) \rightarrow \infty$

**Proof:** Let  $k > 0$  be any given real number.

Choose  $m$  to be any natural number such that  $m > \sqrt{k}$

Then  $n^2 > k$  for all  $n > m$

$\therefore (n^2) \rightarrow \infty$

**Definition.** A sequence  $(a_n)$  is said to diverge to  $-\infty$  if given any real number  $k < 0$  there exists

$m \in \mathbb{N}$  such that that  $a_n < k$  for all  $n \geq m$ . In symbols we write

$\lim_{n \rightarrow \infty} a_n = -\infty$ , or  $(a_n) \rightarrow -\infty$

$n \rightarrow \infty$

**Note.**  $(a_n) \rightarrow -\infty$  iff given any real number  $k < 0$ , there exists  $m \in \mathbb{N}$  such that  $a_n \in (-\infty, k)$  for all  $n \geq m$

A sequence  $(a_n)$  is said to be **divergent** if either  $(a_n) \rightarrow \infty$  or  $(a_n) \rightarrow -\infty$

### Theorem. 2.3

$(a_n) \rightarrow -\infty$  iff  $(-a_n) \rightarrow \infty$

**Proof.**

Let  $(a_n) \rightarrow \infty$

Let  $k < 0$  be any given real number. Since  $(a_n) \rightarrow \infty$  there exists  $m \in \mathbb{N}$  such that  $a_n > -k$  for all  $n \geq m$

$\therefore -a_n < k$  for all  $n \geq m$

$\therefore (-a_n) \rightarrow -\infty$

Similarly we can prove that if  $(-a_n) \rightarrow -\infty$  then  $(a_n) \rightarrow \infty$ .

**Theorem. 2.4**

If  $(a_n) \rightarrow \infty$  and  $a_n \neq 0$  for all  $n \in \mathbb{N}$  then  $(\frac{1}{a_n}) \rightarrow 0$ .

**Proof.** Let  $\epsilon > 0$  be given.

Since  $(a_n) \rightarrow \infty$ , there exists  $m \in \mathbb{N}$  such that  $a_n > 1/\epsilon$  for all  $n \geq m$

$$\therefore \frac{1}{a_n} < \epsilon \text{ for all } n \geq m$$

$$\left| \frac{1}{a_n} \right| < \epsilon \text{ for all } n \geq m$$

Hence  $(\frac{1}{a_n}) \rightarrow 0$

**Note.** The converse of the above theorem is not true. For example, consider the sequence  $(a_n)$  where

$$a_n = (-1)^n / n. \text{ Clearly } (a_n) \rightarrow 0$$

Now  $(1/a_n) = (n / (-1)^n) = -1, 2, -3, 4, \dots$  which neither converges nor diverges to  $\infty$  or  $-\infty$

Thus if a sequence  $(a_n) \rightarrow 0$ , then the sequence  $(1/a_n) \rightarrow 0$  need not converge or diverge.

**Theorem:2.5**

If  $(a_n) \rightarrow 0$  and  $(a_n) > 0$  for all  $n \in \mathbb{N}$ , then  $(\frac{1}{a_n}) \rightarrow \infty$

**Proof.**

Let  $k > 0$  be any given real number.

Since  $(a_n) \rightarrow 0$  there exists  $m \in \mathbb{N}$  such that  $|a_n| < 1/k$  for all  $n \geq m$

$\therefore a_n < 1/k$  for all  $n \geq m$  ( since  $a_n > 0$  )

Therefore  $1/a_n > k$  for all  $n \geq m$

Hence  $(1/a_n) \rightarrow \infty$

**Theorem:2.6**

Any sequence  $(a_n)$  diverging to  $\infty$  is bounded below but not bounded above.

**Proof.**

Let  $(a_n) \rightarrow \infty$ . Then for any given real number  $k > 0$  there exists  $m \in \mathbb{N}$  such that  $a_n > k$  for all  $n \geq m$ ..... (1)

$\therefore k$  is not an upper bound of the sequence  $(a_n)$

$\therefore (a_n)$  is not bounded above

Now let  $l = \min \{ a_1, a_2, \dots, a_m, k \}$ .

From (1) we see that  $a_n \geq l$  for all  $n$ .

$\therefore (a_n)$  is bounded below

**Theorem:2.7**

Any sequence  $(a_n)$  diverging to  $-\infty$  is bounded above but not bounded below.

Proof is similar to that of the previous theorem

**Note 1.** The converse of the above theorem is not true. For example, the function

$f : \mathbb{N} \rightarrow \mathbb{R}$  defined by

$$f(n) = \begin{cases} 0 & \text{if } n \text{ is odd} \\ \frac{1}{2}n & \text{if } n \text{ is even} \end{cases}$$

Determines the sequence 0,1,0,2,0,3,.....which is bounded below and not bounded above. Also for any real number  $k > 0$ , we cannot find a natural number  $m$  such that  $a_n > k$  for all  $n \geq m$ .

Hence this sequence does not diverge to  $\infty$ .

Similarly  $f: \mathbb{N} \rightarrow \mathbb{R}$  given by  $f(n) = \begin{cases} 0 & \text{if } n \text{ is odd} \\ \frac{1}{2}n & \text{if } n \text{ is even} \end{cases}$

Determines the sequence 0, -1, 0, -2, 0, ..... which is bounded above and not bounded below. However this sequence does not diverge to  $-\infty$ .

**Oscillating sequence**

**Definition:** A sequence  $(a_n)$  which is neither convergent nor divergent to  $\infty$  or  $-\infty$  is said to be an

oscillating sequence. An oscillating sequence which is bounded is said to be finitely oscillating. An oscillating sequence which is unbounded is said infinitely oscillating.

**Examples.**

1. Consider the sequence  $((-1)^n)$ . Since this sequence is bounded it cannot to  $\infty$  or  $-\infty$  (by theorems). Also this sequence is not convergent. Hence  $((-1)^n)$  is a finitely oscillating sequence.

2. The function  $f : \mathbb{N} \rightarrow \mathbb{R}$  defined by

$$f(n) = \begin{cases} 0 & \text{if } n \text{ is odd} \\ \frac{1}{2}(1 - n) & \text{if } n \text{ is even} \end{cases} \quad \text{determines the sequence } 0, 1, -1, 2, -2, 3, \dots \text{ The}$$

range of this sequence is  $\mathbb{Z}$ . Hence it cannot converge or diverge to  $\pm\infty$ . This sequence is infinitely oscillating.

**The Algebra of limits**

In this section we prove a few simple theorems for sequences which are very useful in calculating limits of sequences.

**Theorem: 2.8**

If  $(a_n) \rightarrow a$  and  $(b_n) \rightarrow b$  then  $(a_n + b_n) \rightarrow a + b$ .

**Proof:**

Let  $\epsilon > 0$  be given.

Now  $|a_n + b_n - a - b| = |a_n - a + b_n - b| \leq |a_n - a| + |b_n - b|, \dots(1)$

Since  $(a_n) \rightarrow a$ , there exist a natural number  $n_1$  such that  $|a_n - a| < 1/2 \epsilon$  for all  $n \geq n_1, \dots(2)$

Since  $(b_n) \rightarrow b$ , there exist a natural number  $n_2$  such that  $|b_n - b| < 1/2 \epsilon$  for all  $n \geq n_2, \dots(3)$

Let  $m = \max\{n_1, n_2\}$

Then  $|a_n + b_n - a - b| < 1/2\epsilon + 1/2\epsilon = \epsilon$  for all  $n \geq m$ . (by (1),(2)and (3))  
 $\therefore (a_n + b_n) \rightarrow a + b$ .

**Note.** Similarly we can prove that  $(a_n - b_n) \rightarrow a - b$ .

**Theorem:2.9**

If  $(a_n) \rightarrow a$  and  $k \in \mathbb{R}$  then  $(k a_n) \rightarrow k a$ .

**Proof:**

If  $k = 0$ ,  $(k a_n)$  is the constant sequence  $0, 0, 0, \dots$ . And hence the result is trivial.

Now , let  $k \neq 0$ .

Then  $|k a_n - k a| = |k| |a_n - a| \dots \dots \dots (1)$

Let  $\epsilon > 0$  be given.

Since  $(a_n) \rightarrow a$ , there exist  $m \in \mathbb{N}$  such that

$|a_n - a| < \epsilon/|k|$  for all  $n \geq m \dots \dots \dots (2)$

$\therefore |k a_n - k a| < \epsilon$  for all  $n \geq m$  (by 1 and 2).

$\therefore (k a_n) \rightarrow k a$ .

**Theorem: 2.10**

If  $(a_n) \rightarrow a$  and  $(b_n) \rightarrow b$  then  $(a_n b_n) \rightarrow ab$ .

**Proof.**

Let  $\epsilon > 0$  be given.

Now,  $|a_n b_n - ab| = |a_n b_n - a_n b + a_n b - ab|$

$\leq |a_n b_n - a_n b| + |a_n b - ab|$

$= |a_n| |b_n - b| + |b| |a_n - a| \dots \dots (1)$

Also, since  $(a_n) \rightarrow a$ ,  $(a_n)$  is a bounded sequences.

$\therefore$  There exist a real number  $k > 0$  such that  $|a_n| \leq k$  for all  $n \dots \dots \dots (2)$

Using (1) and (2) we get

$|a_n b_n - ab| \leq k |b_n - b| + |b| |a_n - a| \dots \dots \dots (3)$

Now since  $(a_n) \rightarrow a$ , there exist a natural number  $n_1$  such that

$|a_n - a| > \epsilon/2 |b|$  for all  $n \geq n_1 \dots \dots \dots (4)$

Since  $(b_n) \rightarrow b$ , there exist a natural number  $n_2$  such that

$|a_n - a| > \epsilon/2 |b|$  for all  $n \geq n_2 \dots \dots \dots (5)$

Let  $m = \max\{n_1, n_2\}$ .

Then  $|a_n b_n - ab| < k (\epsilon/2k) + |b| (\epsilon/2 |b|) = \epsilon$  for all  $n \geq m$  (by (3),(4)and(5))

Hence  $(a_n b_n) \rightarrow ab$

**Theorem: 2.11**

If  $(a_n) \rightarrow a$  and  $a_n \neq 0$  for all  $n$  and  $a \neq 0$  then  $(\frac{1}{a_n}) \rightarrow \frac{1}{a}$

**Proof:**

Let  $\epsilon > 0$  be given.

We have  $|1/a_n - 1/a| = \left| \frac{a_n - a}{a_n a} \right| = \frac{1}{|a_n| |a|} |a_n - a| \dots \dots \dots (1)$

Now,  $a \neq 0$ . Hence  $|a| > 0$

Since  $(a_n) \rightarrow a$ , there exists  $n_1 \in \mathbb{N}$  such that  $|a_n - a| < \frac{1}{2}|a|$  for all  $n \geq n_1$

Hence  $|a_n| > \frac{1}{2}|a|$  for all  $n \geq n_1$  .....(2)

Using (1) and (2) we get

$$\left| \frac{1}{a_n} - \frac{1}{a} \right| < \frac{2}{|a|^2} |a_n - a| \text{ for all } n \geq n_1 \dots \dots (3)$$

Now since  $(a_n) \rightarrow a$ , there exists  $n_2 \in \mathbb{N}$  such that

$$|a_n - a| < \frac{1}{2}|a|^2 \varepsilon \text{ for all } n \geq n_2 \dots \dots (4)$$

Let  $m = \max \{n_1, n_2\}$ .

$$\left| \frac{1}{a_n} - \frac{1}{a} \right| < \frac{2}{|a|^2} \frac{1}{2} |a|^2 \varepsilon = \varepsilon \text{ for all } n \geq m$$

Therefore  $(1/a_n) \rightarrow 1/a$

**Corollary:**

Let  $(a_n) \rightarrow a$  and  $(b_n) \rightarrow b$  where  $b_n \neq 0$  for all  $n$  and  $b \neq 0$ .

$$\text{Then } \begin{pmatrix} a_n \\ b_n \end{pmatrix} \rightarrow \begin{pmatrix} a \\ b \end{pmatrix}$$

**Proof:**

$$\begin{pmatrix} 1 \\ b_n \end{pmatrix} \rightarrow \begin{pmatrix} 1 \\ b \end{pmatrix} \text{ (since If } (a_n) \rightarrow a \text{ and } a_n \neq 0 \text{ for all } n \text{ and } a \neq 0 \text{ then } \left(\frac{1}{a_n}\right) \rightarrow \frac{1}{a})$$

$$\begin{pmatrix} a_n \\ b_n \end{pmatrix} \rightarrow \begin{pmatrix} a \\ b \end{pmatrix} \text{ (since If } (a_n) \rightarrow a \text{ and } (b_n) \rightarrow b \text{ then } (a_n b_n) \rightarrow ab)$$

**Theorem: 2.12**

If  $(a_n) \rightarrow a$  then  $(|a_n|) \rightarrow |a|$ .

**Proof:**

Let  $\epsilon > 0$  be given

Now  $||a_n| - |a|| \leq |a_n - a| \dots\dots\dots (1)$

Since  $(a_n) \rightarrow a$  there exist  $m \in \mathbf{N}$  such that  $|a_n - a| < \epsilon$  for all  $n \geq m$ .

Hence from (1) we get  $||a_n| - |a|| < \epsilon$  for all  $n \geq m$ .

Hence  $(|a_n|) \rightarrow (a)$ .

**Theorem: 2.13**

If  $(a_n) \rightarrow a$  and  $a_n \geq 0$  for all  $n$  then  $a \geq 0$ .

**Proof.**

Suppose  $a < 0$ . Then  $-a > 0$ .

Choose  $\epsilon$  such that  $0 < \epsilon < -a$  so that  $a + \epsilon < 0$ .

Now, since  $(a_n) \rightarrow a$ , there exist  $m \in \mathbf{N}$  such that  $|a_n - a| < \epsilon$  for all  $n \leq m$ .

$\therefore a - \epsilon < a_n < a + \epsilon$  for all  $n \leq m$ .

Now, since  $a + \epsilon < 0$ , we have  $a_n < 0$  for all  $n \geq m$  which is a contradiction since  $a_n \geq 0$ .

$\therefore a \geq 0$ .

**Theorem: 2.14**

If  $(a_n) \rightarrow a$ ,  $(b_n) \rightarrow b$  and  $a_n \leq b_n$  for all  $n$ , then  $a \leq b$ .

**Proof.**

Since  $a_n \leq b_n$ , we have  $b_n - a_n \geq 0$  for all  $n$ .

Also  $(b_n - a_n) \rightarrow b - a$  (since If  $(a_n) \rightarrow a$  and  $(b_n) \rightarrow b$  then  $(a_n + b_n) \rightarrow a + b$ )

$\therefore b - a \geq 0$

$\therefore b \geq a$ .

**Theorem: 2.15**

If  $(a_n) \rightarrow l$ ,  $(b_n) \rightarrow l$  and  $a_n \leq c_n \leq b_n$  for all  $n$ , then  $(c_n) \rightarrow l$ .

**Proof.**

Let  $\epsilon > 0$  be given.

Since  $(a_n) \rightarrow l$ , there exist  $n_1 \in \mathbf{N}$  such that  $l - \epsilon < a_n < l + \epsilon$  for all  $n \geq n_1$ .

Similarly, there exist  $n_2 \in \mathbf{N}$  such that  $l - \epsilon < b_n < l + \epsilon$  for all  $n \geq n_2$ .

Let  $m = \max \{n_1, n_2\}$ .

$\therefore -\epsilon < a_n \leq c_n \leq b_n < l + \epsilon$  for all  $n \geq m$ .

$\therefore -\epsilon < c_n < l + \epsilon$  for all  $n \geq m$ .

$\therefore |c_n - l| < \epsilon$  for all  $n \geq m$ .

$\therefore (c_n) \rightarrow l$ .

**Theorem: 2.16**

If  $(a_n) \rightarrow a$  and  $a_n \geq 0$  for all  $n$  and  $a \neq 0$ , then  $(\sqrt{a_n}) \rightarrow \sqrt{a}$ .

**Proof.**

Since  $a_n \geq 0$  for all  $n$ ,  $a \geq 0$  (since If  $(a_n) \rightarrow a$  and  $a_n \geq 0$  for all  $n$  then  $a \geq 0$ )

Now,  $|\sqrt{a_n} - \sqrt{a}| = \left| \frac{a_n - a}{\sqrt{a_n} + \sqrt{a}} \right|$

Since  $(a_n) \rightarrow a \neq 0$ , we obtain  $a_n > \frac{1}{2}a$  for all  $n \geq n_1$

$$\sqrt{a_n} > \sqrt{\left(\frac{1}{2}\right)a} \text{ for all } n \geq n_1$$

$$|\sqrt{a_n} - \sqrt{a}| < \frac{\sqrt{2}}{(\sqrt{2}+1)\sqrt{a}} |a_n - a| \text{ for all } n \geq n_1 \dots \dots \dots (1)$$

Now, let  $\epsilon > 0$  be given.

Since  $(a_n) \rightarrow a$ , there exist  $n_2 \in \mathbf{N}$  such that

$$|a_n - a| < \epsilon \sqrt{a} (\sqrt{2} + 1) / \sqrt{2} \text{ for all } n \geq n_2 \dots \dots \dots (2)$$

Let  $m = \max \{n_1, n_2\}$ .

Then  $|\sqrt{a_n} - \sqrt{a}| < \epsilon$  for all  $n \geq m$  (by 1 and 2).

$$\therefore (\sqrt{a_n}) \rightarrow \sqrt{a}.$$

**Theorem: 2.17**

If  $(a_n) \rightarrow \infty$  and  $(b_n) \rightarrow \infty$  then  $(a_n + b_n) \rightarrow \infty$ .

**Proof.**

Let  $k > 0$  be any given real number.

Since  $(a_n) \rightarrow \infty$ , there exists  $n_1 \in \mathbf{N}$  such that  $a_n > \frac{1}{2}k$  for all  $n \geq n_1$ .

Similarly there exists  $n_2 \in \mathbf{N}$  such that  $b_n > \frac{1}{2}k$  for all  $n \geq n_2$ .

Let  $m = \max \{n_1, n_2\}$ .

Then  $a_n + b_n > k$  for all  $n \geq m$ .

$$\therefore (a_n + b_n) \rightarrow \infty.$$

**Theorem: 2.18**

If  $(a_n) \rightarrow \infty$  and  $(b_n) \rightarrow \infty$  then  $(a_n b_n) \rightarrow \infty$ .

**Proof.**

Let  $k > 0$  be any given real number.

Since  $(a_n) \rightarrow \infty$ , there exist  $n_1 \in \mathbf{N}$  such that  $a_n > \sqrt{k}$  for all  $n \geq n_1$ .

Similarly there exists  $n_2 \in \mathbf{N}$  such that  $b_n > \sqrt{k}$  for all  $n \geq n_2$ .

Let  $m = \max \{n_1, n_2\}$ .

Then  $a_n b_n > k$  for all  $n \geq m$ .

$$\therefore (a_n b_n) \rightarrow \infty.$$

**Theorem: 2.19**

Let  $(a_n) \rightarrow \infty$  then

(i) If  $c > 0$ ,  $(c a_n) \rightarrow \infty$

(ii) If  $c < 0$ ,  $(c a_n) \rightarrow -\infty$

**Proof.**

(i) Let  $c > 0$ .

Let  $k > 0$  be any given real number.

Since  $(a_n) \rightarrow \infty$ , there exist  $m \in \mathbf{N}$  such that  $a_n > k/c$  for all  $n \geq m$ .

$$\therefore c a_n > k \text{ for all } n \geq m.$$

$$\therefore (c a_n) \rightarrow \infty.$$

(ii) Let  $c < 0$ .

Let  $k < 0$  be any given real number. Then  $\bar{k}/c > 0$ .

$\therefore$  There exists  $m \in \mathbf{N}$  such that  $a_n > \bar{k}/c$  for all  $n \geq m$ .

$\therefore c a_n < k$  for all  $n \geq m$  (since  $c < 0$ ).

$$\therefore (c a_n) \rightarrow -\infty.$$

**Theorem: 2.20**

If  $(a_n) \rightarrow \infty$  and  $(b_n)$  is bounded then  $(a_n + b_n) \rightarrow \infty$ .

**Proof.**

Since  $(b_n)$  is bounded, there exists a real number  $m < 0$  such that  $b_n > m$  for all  $n$ .

..... (1)

Now, let  $k > 0$  be any real number.

Since  $m < 0$ ,  $k - m > 0$ .

Since  $(a_n) \rightarrow \infty$ , there exists  $n_0 \in \mathbf{N}$  such that  $a_n > k - m$  for all  $n \geq n_0$ ..... (2)

$\therefore a_n + b_n > k - m + m = k$  for all  $n \geq n_0$  (by 1 and 2).

$\therefore (a_n + b_n) \rightarrow \infty$ .

**Solved Problems.**

1. Show that  $\lim_{n \rightarrow \infty} \frac{3n^2 + 2n + 5}{6n^2 + 4n + 7} = \frac{1}{2}$

**Solution:**

$$\frac{3n^2 + 2n + 5}{6n^2 + 4n + 7} = \frac{3 + \frac{2}{n} + \frac{5}{n^2}}{6 + \frac{4}{n} + \frac{7}{n^2}}$$

Now,  $\lim_{n \rightarrow \infty} (3 + \frac{2}{n} + \frac{5}{n^2}) = 3 + 2 \lim_{n \rightarrow \infty} \frac{1}{n} + 5 \lim_{n \rightarrow \infty} \frac{1}{n^2} = 3 + 0 + 0 = 3$

Similarly,  $\lim_{n \rightarrow \infty} (6 + \frac{4}{n} + \frac{7}{n^2}) = 6$

$$\begin{aligned} \lim_{n \rightarrow \infty} a_n &= \lim_{n \rightarrow \infty} \frac{3 + \frac{2}{n} + \frac{5}{n^2}}{6 + \frac{4}{n} + \frac{7}{n^2}} \\ &= \frac{3}{6} \\ &= \frac{1}{2} \end{aligned}$$

2. Show that  $\lim_{n \rightarrow \infty} (\frac{1^2 + 2^2 + \dots + n^2}{n^3}) = \frac{1}{3}$

**Solution:**

We know that  $1^2 + 2^2 + \dots + n^2 = \frac{n(n+1)(2n+1)}{6}$

$$\begin{aligned} \lim_{n \rightarrow \infty} (\frac{1^2 + 2^2 + \dots + n^2}{n^3}) &= \lim_{n \rightarrow \infty} \frac{n(n+1)(2n+1)}{6n^3} \\ &= \lim_{n \rightarrow \infty} \frac{1}{6} (1 + \frac{1}{n})(2 + \frac{1}{n}) \\ &= 1/3 \end{aligned}$$

3. Show that  $\lim_{n \rightarrow \infty} \frac{n}{\sqrt{(n^2+1)}} = 1$

**Solution:**

$$\begin{aligned} \lim_{n \rightarrow \infty} \frac{n}{\sqrt{(n^2+1)}} &= \lim_{n \rightarrow \infty} \frac{1}{\sqrt{(1 + \frac{1}{n^2})}} \\ &= \frac{1}{\sqrt{\lim_{n \rightarrow \infty} (1 + \frac{1}{n^2})}} \end{aligned}$$

$$=$$

$$=$$

$$= 1$$

4. Show that if  $(a_n) \rightarrow 0$  and  $(b_n)$  is bounded, then  $(a_n b_n) \rightarrow 0$ .

**Solution.**

Since  $(b_n)$  is bounded, there exists  $k > 0$  such that  $|b_n| \leq k$  for all  $n$ .

$$\therefore |a_n b_n| \leq k |a_n|.$$

Now, let  $\epsilon > 0$  be given.

Since  $(a_n) \rightarrow 0$  there exists  $m \in \mathbb{N}$  such that  $|a_n| < \epsilon/k$  for all  $n \geq m$ .

$$\therefore |a_n b_n| < \epsilon \text{ for all } n \geq m.$$

$$\therefore (a_n b_n) \rightarrow 0.$$

5. Show that  $\lim_{n \rightarrow \infty} \frac{\sin n}{n} = 0$

**Solution:**

$$|\sin n| \leq 1 \text{ for all } n.$$

$\therefore (\sin n)$  is a bounded sequences

Also,  $(1/n) \rightarrow 0$

$$\therefore \left(\frac{\sin n}{n}\right) \rightarrow 0 \quad (\text{by problem 4}).$$

6. Show that  $\lim_{n \rightarrow \infty} (a^{1/n}) = 1$  where  $a > 0$  is any real number.

**Solution.**

Case (i) Let  $a = 1$ . Then  $a^{1/n} = 1$  for each  $n$ . Hence  $(a^{1/n}) \rightarrow 1$

Case (ii) Let  $a > 1$ . Then  $a^{1/n} > 1$ .

Let  $a^{1/n} = 1 + h_n$  where  $h_n > 0$ .

$$\text{Therefore } a = (1 + h_n)^2$$

$$= 1 + nh_n + \dots + h_n^n$$

$$> 1 + nh_n$$

Therefore,  $h_n < a - 1/n$

Therefore,  $0 < h_n < a - 1/n$

$$\text{Hence } \lim_{n \rightarrow \infty} h_n = 0$$

Therefore,  $(a^{1/n}) = (1 + h_n) \rightarrow 1$ .

Case (iii)

Let  $0 < a < 1$

Then  $1/a > 1$

Therefore,  $(1/a)^{1/n} \rightarrow 1$  (By case (i))

$$\left(\frac{1}{a}\right)^n \rightarrow 1$$

$$(a^{1/n})^n \rightarrow 1$$

7. Show that  $\lim_{n \rightarrow \infty} (n)^{1/n} = 1$ .

**Solution.**

Clearly  $n^{1/n} \geq 1$  for all  $n$ .

Let  $n^{1/n} = 1 + h_n$  where  $h_n \geq 0$

Then  $n = (1+h_n)^n$

$$= 1 + nh_n + nC_2 h_n^2 + \dots + h_n^n$$

$$= \frac{1}{2}n(n-1)h_n^2$$

$$\text{Therefore, } h_n^2 < \frac{2}{(n-1)}$$

$$h_n < \sqrt{\frac{2}{n-1}}$$

$$\text{Since } \sqrt{\frac{2}{n-1}} \rightarrow 0 \text{ and } h_n \geq 0, (h_n) \rightarrow 0$$

$$\text{Hence } (n^{1/n}) = (1+h_n) \rightarrow 1.$$

8. Give an example to show that if  $(a_n)$  is a sequence diverging to  $\infty$  and  $(b_n)$  is sequence diverging to  $-\infty$  then  $(a_n + b_n)$  need not be a divergent sequence.

**Solution.**

Let  $(a_n) = (n)$  and  $(b_n) = (-n)$ .

Clearly  $(a_n) \rightarrow \infty$  and  $(b_n) \rightarrow -\infty$ .

However  $(a_n + b_n)$  is the constant sequence  $0, 0, 0, \dots$  Which converges to 0.

**UNIT - III**  
**BEHAVIOUR OF MONOTONIC SEQUENCES**

**Theorem: 3.1**

- i. A monotonic increasing sequence which is bounded above converges to its l.u.b.
- ii. A monotonic increasing sequence which is bounded above diverges to  $\infty$ .
- iii. A monotonic decreasing sequence which is bounded below converges to its g.l.b.
- iv. A monotonic decreasing sequence which is bounded below diverges to  $-\infty$ .

**Proof:**

(i) Let  $(a_n)$  be a monotonic increasing sequence which is bounded above.

Let  $k$  be the l.u.b of the sequence.

Then  $a_n \leq k$  for all  $n$ .

Let  $\epsilon > 0$  be given

Therefore,  $k - \epsilon < k$  and hence  $k - \epsilon$  is not an upper bound of  $(a_n)$

Hence, there exists  $a_m$  such that  $a_m > k - \epsilon$ .

Now, since  $(a_n)$  is monotonic increasing  $a_n \geq a_m$  for all  $n > m$

Hence  $a_n > k - \epsilon$  for all  $n \geq m$ .....(2)

Therefore  $k - \epsilon < a_n \leq k$  for all  $n \geq m$ .(by 1 and 2)

Therefore  $|a_n - k| < \epsilon$  for all  $n \geq m$ .

Therefore  $(a_n) \rightarrow k$ .

(ii) Let  $(a_n)$  be a monotonic increasing sequence which is not bounded above.

Let  $k > 0$  be any real number.

since  $(a_n)$  is not bounded, there exists  $m \in \mathbb{N}$  such that  $a_m > k$ .

Also  $a_n \geq a_m$  for all  $n \geq m$ .

$\therefore a_n > k$  for all  $n \geq m$

Hence,  $(a_n) \rightarrow \infty$

Proof of (iii) is similar to that of (i)

Proof of (iv) is similar to that of (ii)

**Note:**

The above theorem shows that a monotonic sequence either converges or diverges. Thus a Monotonic sequence cannot be an oscillating sequence.

**Solved Problems:**

1. Let  $a_n = 1 + \frac{1}{1!} + \frac{1}{2!} + \dots + \frac{1}{n!}$ . Show that  $\lim_{n \rightarrow \infty} a_n$  exists and lies between 2 and 3.

**Solution:**

Clearly  $(a_n)$  is a monotonic increasing sequence

$$\begin{aligned}
\text{Also, } a_n &= 1 + \frac{1}{1!} + \frac{1}{2!} + \dots + \frac{1}{n!} \\
&\leq 1 + 1 + \frac{1}{2} + \frac{1}{2^2} + \dots + \frac{1}{2^{n-1}} \\
&= 1 + \left( \frac{1 - \frac{1}{2^n}}{1 - \frac{1}{2}} \right) \\
&= 1 + 2 \left( 1 - \frac{1}{2^n} \right) \\
&= 3 - \frac{1}{2^{n-1}} < 3
\end{aligned}$$

$$\therefore a_n < 3$$

$\therefore (a_n)$  is bounded above

Therefore,  $\lim_{n \rightarrow \infty} a_n$  exists

Also  $2 < a_n < 3$  for all  $n$ .

$$\therefore 2 < \lim_{n \rightarrow \infty} a_n < 3$$

Hence the result.

1. Show that the sequence  $(1 + \frac{1}{n})^n$  converges.

**Solution:**

$$\text{Let } a_n = \left(1 + \frac{1}{n}\right)^n$$

By binomial theorem,

$$\begin{aligned}
a_n &= 1 + 1 + \binom{n(n-1)}{2!} \frac{1}{n^2} + \binom{n(n-1)(n-2)}{3!} \frac{1}{n^3} + \dots + \frac{1}{n^n} \\
&= 1 + 1 + \frac{1}{2!} \left(1 - \frac{1}{n}\right) + \frac{1}{3!} \left(1 - \frac{1}{n}\right) \left(1 - \frac{2}{n}\right) + \dots + \frac{1}{n!} \left(1 - \frac{1}{n}\right) \left(1 - \frac{2}{n}\right) \dots \left(1 - \frac{n-1}{n}\right) \\
&< 1 + 1 + \frac{1}{2!} + \frac{1}{3!} + \dots + \frac{1}{n!} \\
&< 3 \text{ (by problem 1)}
\end{aligned}$$

Therefore,  $(a_n)$  is bounded above.

Also,

$$\begin{aligned}
a_{n+1} &= 1 + 1 + \frac{1}{2!} \left(1 - \frac{1}{n+1}\right) + \frac{1}{3!} \left(1 - \frac{1}{n+1}\right) \left(1 - \frac{2}{n+1}\right) + \dots + \frac{1}{(n+1)!} \left(1 - \frac{1}{n+1}\right) \dots \left(1 - \frac{n}{n+1}\right) \\
&> 1 + 1 + \frac{1}{2!} \left(1 - \frac{1}{n}\right) + \frac{1}{3!} \left(1 - \frac{1}{n}\right) \left(1 - \frac{2}{n}\right) + \dots + \frac{1}{n!} \left(1 - \frac{1}{n}\right) \dots \left(1 - \frac{n-1}{n}\right)
\end{aligned}$$

$$\therefore a_{n+1} > a_n$$

$\therefore (a_n)$  is monotonic increasing.

$\therefore (a_n)$  is a convergent sequence.

### Theorem: 3.2 (Cauchy's First Limit Theorem)

If  $(a_n) \rightarrow l$  then  $\left(\frac{a_1 + a_2 + \dots + a_n}{n}\right) \rightarrow l$ .

**Proof:**

Case (i).

Let  $l = 0$

$$\text{Let } b_n = \frac{a_1 + a_2 + \dots + a_n}{n}$$

Let  $\varepsilon > 0$  be given.

Since  $(a_n) \rightarrow 0$  there exists  $m \in \mathbb{N}$  such that  $|a_n| < (1/2)\varepsilon$  for all  $n \geq m$ .....(1)

Now let  $n \geq m$

$$\begin{aligned} \text{Then } |b_n| &= \left| \frac{a_1 + a_2 + \dots + a_m + a_{m+1} + \dots + a_n}{n} \right| \\ &\leq \frac{|a_1| + |a_2| + \dots + |a_m|}{n} + \frac{|a_{m+1}| + \dots + |a_n|}{n} \\ &= \frac{k}{n} + \frac{|a_{m+1}| + \dots + |a_n|}{n} \text{ where } k = |a_1| + |a_2| + \dots + |a_m| \end{aligned}$$

$$< \frac{k}{n} + \left(\frac{n-m}{n}\right) \frac{\varepsilon}{2} \text{ (by (1))}$$

$$< \frac{k}{n} + \frac{\varepsilon}{2} \text{ (Since } \frac{n-m}{n} < 1) \dots \dots (2)$$

Now since  $(k/n) \rightarrow 0$ , there exists  $n_0 \in \mathbb{N}$  such that  $k/n < (1/2)\varepsilon$  for all  $n \geq n_0$ ..... (3)

Let  $n_1 = \max\{m, n_0\}$

Then  $|b_n| < \varepsilon$  for all  $n \geq n_1$  (using 2 and 3)

Therefore  $(b_n) \rightarrow 0$

Case (ii)

Let  $l \neq 0$

Since  $(a_n) \rightarrow l$ ,  $(a_n - l) \rightarrow 0$

$$\therefore \left( \frac{(a_1 - l) + (a_2 - l) + \dots + (a_n - l)}{n} \right) \rightarrow 0 \text{ (by case (i))}$$

$$\therefore \left( \frac{a_1 + a_2 + \dots + a_n - nl}{n} \right) \rightarrow 0$$

$$\therefore \left( \frac{a_1 + a_2 + \dots + a_n}{n} - l \right) \rightarrow 0$$

$$\therefore \left( \frac{a_1 + a_2 + \dots + a_n}{n} \right) \rightarrow l$$

**Theorem: 3.3 (Cesaro's theorem)**

If  $(a_n) \rightarrow a$  and  $(b_n) \rightarrow b$  then  $\left( \frac{a_1 b_n + a_2 b_{n-1} + \dots + a_n b_1}{n} \right) \rightarrow ab$

**Proof:**

$$\text{Let } c_n = \frac{a_1 b_n + a_2 b_{n-1} + \dots + a_n b_1}{n}$$

Now put  $a_n = a + r_n$  so that  $(r_n) \rightarrow 0$

$$\text{Then } c_n = \frac{(a+r_1)b_n + \dots + (a+r_n)b_1}{n}$$

$$= \frac{a(b_1 + \dots + b_n)}{n} + \frac{r_1 b_n + \dots + r_n b_1}{n}$$

Now, by Cauchy's first limit theorem,  $\left(\frac{b_1 + \dots + b_n}{n}\right) \rightarrow l$

$$\therefore \left(\frac{a(b_1 + b_2 + \dots + b_n)}{n}\right) \rightarrow ab$$

Hence it is enough if we prove that  $\left(\frac{r_1 b_n + \dots + r_n b_1}{n}\right) \rightarrow 0$

Since, since  $(b_n) \rightarrow b$ ,  $(b_n)$  is a bounded sequence.

Therefore, there exists a real number  $k > 0$  such that  $|b_n| \leq k$  for all  $n$ .

$$\therefore \left|\frac{r_1 b_n + \dots + r_n b_1}{n}\right| \leq k \left|\frac{r_1 + \dots + r_n}{n}\right|$$

Since  $(r_n) \rightarrow 0$ ,  $\left(\frac{r_1 b_n + \dots + r_n b_1}{n}\right) \rightarrow 0$

$$\left(\frac{r_1 b_n + \dots + r_n b_1}{n}\right) \rightarrow 0$$

Hence the theorem.

### Theorem: 3.4 (Cauchy's Second Limit Theorem)

Let  $(a_n)$  be a sequence of positive terms. Then  $\lim_{n \rightarrow \infty} a_n^{\frac{1}{n}} = \lim_{n \rightarrow \infty} \frac{a_{n+1}}{a_n}$  provided the limit on the right hand side exists, whether finite or infinite.

**Proof:**

Case(i)  $\lim_{n \rightarrow \infty} \frac{a_{n+1}}{a_n} = l$ , finite.

Let  $\varepsilon > 0$  be any given real number.

Then there exists  $m \in \mathbb{N}$  such that  $l - \frac{1}{2}\varepsilon < \frac{a_{n+1}}{a_n} < l + \frac{1}{2}\varepsilon$  for all  $n \geq m$

Now choose  $n \geq m$

$$\text{Then } l - \frac{1}{2}\varepsilon < \frac{a_{m+1}}{a_m} < l + \frac{1}{2}\varepsilon$$

$$l - \frac{1}{2}\varepsilon < \frac{a_{m+2}}{a_{m+1}} < l + \frac{1}{2}\varepsilon$$

.....

.....

$$l - \frac{1}{2}\varepsilon < \frac{a_n}{a_{n-1}} < l + \frac{1}{2}\varepsilon$$

Multiplying these inequalities, we obtain

$$\left(l - \frac{1}{2}\varepsilon\right)^{n-m} < \frac{a_n}{a_m} < \left(l + \frac{1}{2}\varepsilon\right)^{n-m}$$

$$\therefore a_m \frac{\left(l - \frac{1}{2}\varepsilon\right)^n}{\left(l - \frac{1}{2}\varepsilon\right)^m} < a_n < a_m \frac{\left(l + \frac{1}{2}\varepsilon\right)^n}{\left(l + \frac{1}{2}\varepsilon\right)^m}$$

$$\therefore k_1 \left(l - \frac{1}{2}\varepsilon\right)^n < a_n < k_2 \left(l + \frac{1}{2}\varepsilon\right)^n, \text{ Where } k_1, k_2 \text{ are some constants}$$

$$\therefore k_1^{\frac{1}{n}} \left(l - \frac{1}{2}\varepsilon\right) < a_n^{\frac{1}{n}} < k_2^{\frac{1}{n}} \left(l + \frac{1}{2}\varepsilon\right) \dots\dots\dots(1)$$

Now,  $(k_1^{\frac{1}{n}}(l - \frac{1}{2}\epsilon)) \rightarrow l - \frac{1}{2}\epsilon$  (Since  $(k_1^{\frac{1}{n}}) \rightarrow l$ )

$\therefore$  There exists  $n_1 \in \mathbb{N}$  such that  $(l - \frac{1}{2}\epsilon) - \frac{1}{2}\epsilon < k_1^{\frac{1}{n}}(l - \frac{1}{2}\epsilon) < (l - \frac{1}{2}\epsilon) + \frac{1}{2}\epsilon$   
for all  $n \geq n_1$  .....(2)

Similarly, there exists  $n_2 \in \mathbb{N}$  such that  $(l + \frac{1}{2}\epsilon) - \frac{1}{2}\epsilon < k_2^{\frac{1}{n}}(l + \frac{1}{2}\epsilon) < (l + \frac{1}{2}\epsilon) + \frac{1}{2}\epsilon$   
for all  $n \geq n_2$  .....(3)

Let  $n_0 = \max \{m, n_1, n_2\}$ .

Then  $l - \epsilon < k_1^{\frac{1}{n}}(l - \frac{1}{2}\epsilon) < a_n^{\frac{1}{n}} < k_2^{\frac{1}{n}}(l + \frac{1}{2}\epsilon) < l + \epsilon$  for all  $n \geq n_0$  (by 1,2 and 3)

$\therefore l - \epsilon < a_n^{\frac{1}{n}} < l + \epsilon$  for all  $n \geq n_0$

Hence  $(a_n^{\frac{1}{n}}) \rightarrow l$ .

Case (ii):

$$\lim_{n \rightarrow \infty} \frac{a_{n+1}}{a_n} = \infty$$

Then  $\lim_{n \rightarrow \infty} (\frac{1}{a_{n+1}}) / (\frac{1}{a_n}) = 0$

Therefore, By case (i),  $(\frac{1}{a_n})^{\frac{1}{n}} \rightarrow 0$

Hence  $(a_n^{\frac{1}{n}}) \rightarrow \infty$

### Theorem: 3.5

Let  $(a_n)$  be any sequence and  $\lim_{n \rightarrow \infty} \left| \frac{a_n}{a_{n+1}} \right| = l$ . If  $l > 1$ , then  $(a_n) \rightarrow 0$ .

### Theorem: 3.6

Let  $(a_n)$  be any sequence of positive terms and  $\lim_{n \rightarrow \infty} \left( \frac{a_n}{a_{n+1}} \right) = l$ . If  $l < 1$ , then  $(a_n) \rightarrow \infty$ .

### Problems:

1. Show that  $\lim_{n \rightarrow \infty} \frac{1}{n} \left( 1 + \frac{1}{2} + \dots + \frac{1}{n} \right) = 0$

### Solution:

Let  $a_n = 1/n$

We know that  $(a_n) \rightarrow 0$ . Hence by Cauchy's first limit theorem we get

$$\left( \frac{a_1 + a_2 + \dots + a_n}{n} \right) \rightarrow 0$$

2. Show that  $\lim_{n \rightarrow \infty} \frac{n!}{n^n} = 0$

### Solution:

Let  $a_n = \frac{n!}{n^n}$

$$\therefore \left| \frac{a_n}{a_{n+1}} \right| = \frac{n! (n+1)^{n+1}}{n^n (n+1)!}$$

$$\begin{aligned}
&= \left(\frac{n+1}{n}\right)^n \\
&= \left(1 + \frac{1}{n}\right)^n \\
\lim_{n \rightarrow \infty} \left| \frac{a_n}{a_{n+1}} \right| &= \lim_{n \rightarrow \infty} \left(1 + \frac{1}{n}\right)^n \\
&= e > 1
\end{aligned}$$

Hence  $(a_n) \rightarrow 0$

### Subsequence

**Definition.** Let  $(a_n)$  be a sequence. Let  $(n_k)$  be a strictly increasing sequence of natural numbers. Then  $(a_{n_k})$  is called a subsequence of  $(a_n)$ .

**Note.** The terms of a subsequence occur in the same order in which they occur in the original sequence.

### Examples.

- $(a_{2n})$  is a subsequence of any sequence  $(a_n)$ . Note that in this example the interval between any two terms of the subsequence is the same, (i.e.,)  $n_1=2, n_2=4, n_3=6, \dots, n_k=2k$ .
- $(a_{n^2})$  is a subsequence of any sequence  $(a_n)$ . Hence  $a_{n_1} = a_1, a_{n_2} = a_4, a_{n_3} = a_9, \dots$ . Here the interval between two successive terms of the subsequence goes on increasing as  $k$  becomes large. Thus the interval between various terms of a subsequence need not be regular.
- Any sequence  $(a_n)$  is a subsequence of itself.

### Theorem: 3.7

If a sequence  $(a_n)$  converges to  $l$ , then every subsequence  $(a_{n_k})$  of  $(a_n)$  also converges to  $l$ .

### Proof.

Let  $\epsilon > 0$  be given.

Since  $(a_n) \rightarrow l$  there exists  $m \in \mathbb{N}$  such that

$$|a_n - l| < \epsilon \text{ for all } n \geq m. \dots\dots\dots(1)$$

Now choose  $n_{k_0} \geq m$ .

Then  $k \geq k_0 \Rightarrow n_k \geq n_{k_0} (\because (n_k) \text{ is monotonic increasing})$

$$\Rightarrow n_k \geq m.$$

$$\Rightarrow |a_{n_k} - l| < \epsilon \text{ (by 1)}$$

Thus  $|a_{n_k} - l| < \epsilon$  for all  $k \geq k_0$ .

$$\therefore (a_{n_k}) \rightarrow l.$$

**Note 1.** If a subsequence of a sequence converges, then the original sequence need not converge.

### Theorem :3.8

If the subsequences  $(a_{2n-1})$  and  $(a_{2n})$  of a sequence  $(a_n)$  converge to the same limit  $l$

then  $(a_n)$  also converges to  $l$ .

**Proof.**

Let  $\epsilon > 0$  be given. Since  $(a_{2n-1}) \rightarrow l$  there exists  $n_1 \in \mathbb{N}$  such that  $|a_{2n-1} - l| < \epsilon$  for all  $2n - 1 \geq n_1$ .

Similarly there exists  $n_2 \in \mathbb{N}$  such that  $|a_{2n} - l| < \epsilon$  for all  $2n \geq n_2$ .

Let  $m = \max\{n_1, n_2\}$ .

Clearly  $|a_n - l| < \epsilon$  for all  $n \geq m$ .

$\therefore (a_n) \rightarrow l$ .

**Note.** The above result is true even if we have  $l \rightarrow \infty$  or  $-\infty$ .

**Definition.** Let  $(a_n)$  be a sequence. A natural number  $m$  is called a **peak point** of the sequence  $(a_n)$  if  $a_n < a_m$  for all  $n > m$ .

**Example.**

1. For the sequence  $(1/n)$ , every natural number is a peak point and hence the sequence has infinite number of peak point. In general for a strictly monotonic decreasing sequence every natural number is a peak point.
2. Consider the sequence  $1, \frac{1}{2}, \frac{1}{3}, -1, -1, \dots$ . Here  $1, 2, 3$  are the peak points of the sequence.
3. The sequence  $1, 2, 3, \dots$  has no peak point. In general a monotonic increasing sequence has no Peak point.

**Theorem :3.9**

Every sequence  $(a_n)$  has no monotonic subsequence.

**Proof.**

Case (i)

$(a_n)$  has infinite number of peak points. Let the peak points be

$$n_1 < n_2 < \dots < n_k < \dots$$

$$\text{Then } a_{n_1} > a_{n_2} > \dots > a_{n_k} > \dots$$

$\therefore (a_{n_k})$  is a monotonic decreasing subsequence of  $(a_n)$ .

Case (ii)

$(a_n)$  has only a finite number of peak points or no peak points.

Choose a natural number  $n_1$  such that there is no peak point greater than or equal to  $n_1$ .

Since  $n_1$  is not a peak point of  $(a_n)$ , there exists  $n_2 > n_1$  such that  $a_{n_2} \geq a_{n_1}$ .

Again since  $n_2$  is not a peak point, there exist  $n_3 > n_2$  such that  $a_{n_3} \geq a_{n_2}$ .

Repeating this process we get a monotonic increasing subsequence  $(a_{n_k})$  of  $(a_n)$ .

**Theorem : 3.10**

Every bounded sequences has a convergent subsequences.

**Proof.**

Let  $(a_n)$  be a bounded sequence. Let  $(a_{n_k})$  be monotonic subsequence of  $(a_n)$ . since  $(a_n)$  is bounded,  $(a_{n_k})$  is also bounded.

$\therefore (a_{n_k})$  is a bounded monotonic sequence and hence converges.

$\therefore (a_{n_k})$  is a convergent subsequence of  $(a_n)$ .

**Cauchy sequences.**

**Definition.** A sequence  $(a_n)$  is said to be a **Cauchy sequence** if given  $\epsilon > 0$ , there exists  $n_0 \in \mathbb{N}$  such that

$$|a_n - a_m| < \epsilon \text{ for all } n, m \geq n_0.$$

**Note.** In the above definition the condition  $|a_n - a_m| < \epsilon$  for all  $n, m \geq n_0$  can be written in the

following equivalent form, namely,  $|a_{n+p} - a_n| < \epsilon$  for all  $n \geq n_0$  and for all positive integers  $p$ .

**Examples**

1. The sequence  $(1/n)$  is a Cauchy sequence.

**Proof.**

Let  $(a_n) = (1/n)$ .

Let  $\epsilon > 0$  be given.

Now,  $|a_n - a_m| = |1/n - 1/m|$

$\therefore$  If we choose  $n_0$  to be any positive integer greater than  $1/\epsilon$ , we get

$$|a_n - a_m| \leq \epsilon \text{ for all } n, m \geq n_0.$$

$\therefore (1/n)$  is a Cauchy sequence.

2. The sequence  $((-1)^n)$  is not a Cauchy sequence.

**Proof.**

Let  $(a_n) = ((-1)^n)$ .

$$\therefore |a_n - a_{n+1}| = 2.$$

$\therefore$  If  $\epsilon < 2$ , we cannot find  $n_0$  such that  $|a_n - a_{n+1}| < \epsilon$  for all  $n \geq n_0$ .

$\therefore ((-1)^n)$  is not a Cauchy sequence.

3.  $(n)$  is not a Cauchy sequence.

**Proof.**

Let  $(a_n) = (n)$ .

$$\therefore |a_n - a_m| \geq 1 \text{ if } n \neq m.$$

$\therefore$  If we choose  $\epsilon < 1$ , we cannot find  $n_0$  such that  $|a_n - a_m| < \epsilon$  for all  $n, m \geq n_0$ .

$\therefore (n)$  is not a Cauchy sequence.

**Theorem :3.11**

Any convergent sequence is a Cauchy sequence.

**Proof.**

Let  $(a_n) \rightarrow l$ . Then given  $\epsilon > 0$ , there exists  $n_0 \in \mathbf{N}$  such that  $|a_n - l| < (1/2)\epsilon$  for all  $n \geq n_0$

$$\therefore |a_n - a_m| = |a_n - l + l - a_m|$$

$$\leq |a_n - l| + |l - a_m|$$

$$< (1/2)\epsilon + (1/2)\epsilon = \epsilon \quad \text{for all } n, m \geq n_0.$$

$\therefore (a_n)$  is a Cauchy sequence.

### Theorem .3.12

Any Cauchy sequence is a bounded sequence .

#### Proof.

Let  $(a_n)$  be a Cauchy sequence.

Let  $\epsilon > 0$  be given. Then there exists  $n_0 \in \mathbf{N}$  such that  $|a_n - a_m| < \epsilon$  for all  $n, m \geq n_0$ .

$$\therefore |a_n| < |a_{n_0}| + \epsilon \text{ for } n \geq n_0.$$

Now, let  $k = \max \{ |a_1|, |a_2|, \dots, |a_{n_0}| + \epsilon \}$ .

Then  $|a_n| \leq k$  for all  $n$ .

$\therefore (a_n)$  is a bounded sequence.

### Theorem . 3.13

Let  $(a_n)$  be a Cauchy sequence. If  $(a_n)$  has a subsequence  $(a_{n_k})$  converging to  $l$ , then  $(a_n) \rightarrow l$ .

#### Proof.

Let  $\epsilon > 0$  be given. Then there exists  $n_0 \in \mathbf{N}$  such that

$$|a_n - a_m| < (1/2)\epsilon \text{ for all } n, m \geq n_0 \dots (1)$$

$$\text{Also since } (a_{n_k}) \rightarrow l, \text{ there exists } k_0 \in \mathbf{N} \text{ such that } |a_{n_k} - l| < \frac{1}{2}\epsilon \text{ for all } k \geq k_0 \dots (2)$$

Choose  $n_k$  such that  $n_k > n_{k_0}$  and  $n_0$

$$\text{Then } |a_n - l| = |a_n - a_{n_k} + a_{n_k} - l|$$

$$\leq |a_n - a_{n_k}| + |a_{n_k} - l|$$

$$= (1/2)\epsilon + (1/2)\epsilon$$

$$= \epsilon \text{ for all } n \geq n_k.$$

Hence  $(a_n) \rightarrow l$ .

### Theorem : 3.14 (Cauchy's General Principle of Convergence

#### Sequence)

A sequence  $(a_n)$  in  $\mathbf{R}$  is convergent iff it is a Cauchy sequence.

#### Proof.

we have proved that any convergent sequence is a Cauchy sequence.

Conversely, let  $(a_n)$  be a Cauchy sequence in  $\mathbf{R}$ .

$\therefore (a_n)$  is a bounded sequence (Any Cauchy sequence is a bounded sequence)

$\therefore$  There exist a subsequence  $(a_{n_k})$  of  $(a_n)$  such that  $(a_{n_k}) \rightarrow l$

$\therefore (a_n) \rightarrow l$  ( by previous theorem ).

## UNIT - IV SERIES

### Infinite series

**Definition.** Let  $(a_n) = a_1, a_2, \dots, a_n, \dots$  be a sequence of real numbers. Then the formal expression  $a_1 + a_2 + \dots + a_n + \dots$  is called an infinite series of real numbers and is denoted by  $\sum_1^\infty a_n$  or  $\sum a_n$ .

Let  $s_1 = a_1; s_2 = a_1 + a_2; s_3 = a_1 + a_2 + a_3; \dots; s_n = a_1 + a_2 + \dots + a_n$ .

Then  $(s_n)$  is called the sequence of partial sums of the given series  $\sum a_n$ .

The series  $\sum a_n$  is said to converge, diverge or oscillate according as the sequence of partial sums  $(s_n)$  converges, diverges or oscillates.

If  $(s_n) \rightarrow s$ , we say that the series  $\sum a_n$  converges to the sum  $s$ .

We note that the behavior of a series does not change if a finite number of terms are added or altered.

### Examples.

Consider the series  $1 + 1 + 1 + 1 + \dots$ . Here  $s_n = n$ . Clearly the sequence  $(s_n)$  diverges to  $\infty$ . Hence the given series diverges to  $\infty$ .

2. Consider the geometric series  $1 + r + r^2 + \dots + r^n + \dots$

Here,  $s_n = 1 + r + r^2 + \dots + r^{n-1} = \frac{1-r^n}{1-r}$ .

Case (i)  $0 < r < 1$ . Then  $(r^n) \rightarrow 0$

Therefore,  $(s_n) \rightarrow \frac{1}{1-r}$ .  $\therefore$  The given series converges to the sum  $1/(1-r)$

Case (ii)  $r > 1$ .

Then  $s_n = \frac{r^n - 1}{r - 1}$

Also  $(r^n) \rightarrow \infty$  when  $r > 1$

Hence the series diverges to  $\infty$

Case (iii)  $r = 1$ .

Then the series becomes  $1 + 1 + \dots$

$(s_n) = (n)$ . which diverges to  $\infty$ .

Case (iv)  $r = -1$ .

Then the series becomes  $1 - 1 + 1 - 1 + \dots$

$\therefore s_n = \begin{cases} 0 & \text{if } n \text{ is even} \\ 1 & \text{if } n \text{ is odd} \end{cases}$

$\therefore (s_n)$  oscillates finitely.

Hence the given series oscillates finitely.

Case (v) :  $r < -1$ .

$\therefore (r^n)$  oscillates infinitely  
 $\therefore (s_n)$  oscillates infinitely.

Hence the given series oscillates infinitely.

**Note 1.** Let  $\sum a_n$  be a series of positive terms. Then  $(s_n)$  is a monotonic increasing sequence. Hence  $(s_n)$  converges or diverges to  $\infty$  according as  $(s_n)$  is bounded or unbounded. Hence the series  $\sum a_n$  converges or diverges to  $\infty$ . Thus a series of positive terms cannot oscillate.

**Note 2.** Let  $\sum a_n$  be a convergent series of positive terms converging to the sum  $s$ . Then  $s$  is the l. u. b. of  $(s_n)$ . Hence  $s_n \leq s$  for all  $n$ . Also given  $\epsilon > 0$  there exists  $m \in \mathbf{N}$  such that  $s - \epsilon < s_n$  for all  $n \geq m$ . Hence  $s - \epsilon < s_n \leq s$  for all  $n \geq m$ .

**Theorem : 4.1**

Let  $\sum a_n$  be a convergent series converging to the sum  $s$ .

Then  $\lim_{n \rightarrow \infty} a_n = 0$

**Proof.**

$$\lim_{n \rightarrow \infty} a_n = \lim_{n \rightarrow \infty} (s_n - s_{n-1})$$

$$= \lim_{n \rightarrow \infty} s_n - \lim_{n \rightarrow \infty} s_{n-1}$$

$$= s - s = 0.$$

**Theorem . 4.2**

Let  $\sum a_n$  converge to  $a$  and  $\sum b_n$  converge to  $b$ . Then  $\sum (a_n \pm b_n)$  converges to  $a \pm b$  and  $\sum ka_n$  converges to  $ka$ .

**Proof.**

Let  $s_n = a_1 + a_2 + \dots + a_n$  and  $t_n = b_1 + b_2 + \dots + b_n$ . Then  $(s_n) \rightarrow a$  and  $(t_n) \rightarrow b$ .

$$\therefore (s_n \pm t_n) \rightarrow a \pm b$$

Also  $(s_n \pm t_n)$  is the sequence of partial sums of  $\sum (a_n \pm b_n)$

$$\therefore \sum (a_n \pm b_n) \text{ converges to } a \pm b.$$

Similarly  $\sum ka_n$  converges to  $ka$ .

**Theorem 4.3 (Cauchy's general principle of convergence in Series)**

The series  $\sum a_n$  is convergent iff given  $\epsilon > 0$  there exists  $n_0 \in \mathbf{N}$  such that  $|a_{n+1} + a_{n+2} + \dots + a_{n+p}| < \epsilon$  for all  $n \geq n_0$  and for all positive integers  $p$ .

**Proof.**

Let  $\sum a_n$  be a convergent series. Let  $s_n = a_1 + \dots + a_n$ .

$\therefore (s_n)$  is a convergent sequence.

$\therefore (s_n)$  is a Cauchy sequence

$\therefore$  There exists  $n_0 \in \mathbf{N}$  such that  $|s_{n+p} - s_n| < \epsilon$  for all  $n \geq n_0$  and for all  $p \in \mathbf{N}$ .

$\therefore |a_{n+1} + a_{n+2} + \dots + a_{n+p}| < \epsilon$  for all  $n \geq n_0$  and for all  $p \in \mathbf{N}$ .

Conversely if  $|a_{n+1} + a_{n+2} + \dots + a_{n+p}| < \epsilon$  for all  $n \geq n_0$  and for all  $p \in \mathbf{N}$  then  $(s_n)$  is a Cauchy sequence in  $\mathbf{R}$  and hence  $(s_n)$  is convergent.

$\therefore$  The given series converge.

### Solved Problems.

1. Apply Cauchy's general principle of convergence to show that the series  $\sum \frac{1}{n}$  not convergent.

**Solution.** Let  $s_n = 1 + \frac{1}{2} + \dots + \frac{1}{n}$

Suppose the series  $\sum \frac{1}{n}$  is convergent.

$\therefore$  By Cauchy's general principle of convergence, given  $\epsilon > 0$  there exists  $m \in \mathbf{N}$  such that

$|s_{n+p} - s_n| < \epsilon$  for all  $n \geq m$  and for all  $p \in \mathbf{N}$ .

$\left| \left( 1 + \frac{1}{2} + \dots + \frac{1}{n+p} \right) - \left( 1 + \frac{1}{2} + \dots + \frac{1}{n} \right) \right| < \epsilon$  for all  $n \geq m$  and for all  $p \in \mathbf{N}$ .

$\left| \frac{1}{n+1} + \frac{1}{n+2} + \dots + \frac{1}{n+p} \right| < \epsilon$  for all  $n \geq m$  and for all  $p \in \mathbf{N}$ .

In particular if we take  $n = m$  and  $p = m$  we obtain

$$\frac{1}{m+1} + \frac{1}{m+2} + \dots + \frac{1}{m+m} > \frac{1}{2m} + \dots + \frac{1}{2m} = \frac{1}{2}$$

$\therefore \frac{1}{2} < \epsilon$  which is a contradiction since  $\epsilon > 0$  is arbitrary.

$\therefore$  The given series is not convergent.

### **Comparison test**

#### **Theorem 4.4 (Comparison test)**

i). Let  $\sum c_n$  be a convergent series of positive terms. Let  $\sum a_n$  be another series of positive terms. If there exists  $m \in \mathbf{N}$  such that  $a_n \leq c_n$  for all  $n \geq m$ , then  $\sum a_n$  is also convergent.

ii). Let  $\sum d_n$  be a divergent series of positive terms. Let  $\sum a_n$  be another series of positive terms. If there exists  $m \in \mathbf{N}$  such that  $a_n \leq d_n$  for all  $n \geq m$ , then  $\sum a_n$  is also divergent.

#### **Proof:**

(i) Since the convergence or divergence of a series is not altered by the removal of a finite number

of terms we may assume without loss of generality that  $a_n \leq c_n$  for all  $n$ .

Let  $s_n = c_1 + c_2 + \dots + c_n$  and  $t_n = a_1 + a_2 + \dots + a_n$ .

Since  $a_n \leq c_n$  we have  $t_n \leq s_n$ .

Now, Since  $\sum c_n$  is convergent,  $(s_n)$  is a convergent sequence.

$\therefore (s_n)$  is a bounded sequence.

$\therefore$  There exists a real positive number  $k$  such that  $s_n \leq k$  for all  $n$ .

$\therefore t_n \leq k$  for all  $n$

Hence  $(t_n)$  is bounded above.

Also  $(t_n)$  is a monotonic increasing sequence.

$\therefore (t_n)$  converges

$\therefore \sum a_n$  converges.

(ii) Let  $\sum d_n$  diverge and  $a_n \geq d_n$  for all  $n$ .

$\therefore t_n \geq s_n$ .

Now,  $(s_n)$  diverges to  $\infty$ .

$\therefore (s_n)$  is not bounded above.

$\therefore (t_n)$  is not bounded above.

Further  $(t_n)$  is monotonic increasing and hence  $(t_n)$  diverges to  $\infty$ .

$\therefore \sum a_n$  diverges to  $\infty$ .

#### Theorem :4.5

(i) If  $\sum c_n$  converges and if  $\lim_{n \rightarrow \infty} \left(\frac{a_n}{c_n}\right)$  exists and is finite then  $\sum a_n$  also converges.

(ii) If  $\sum \frac{a_n}{c_n} d_n$  diverges and if  $\lim_{n \rightarrow \infty} \left(\frac{a_n}{d_n}\right)$  exists and is greater than zero then  $\sum a_n$  diverges.

#### Proof

(i) .Let  $\lim_{n \rightarrow \infty} \left(\frac{a_n}{c_n}\right) = k$

Let  $\epsilon > 0$  be given. Then there exists  $n \in \mathbf{N}$  such that  $\frac{a_n}{c_n} < k + \epsilon$  for all  $n \geq n_1$ .

$\therefore a_n < (k + \epsilon) c_n$  for all  $n \geq n_1$ .

Also since  $\sum c_n$  is a convergent series,  $\sum (k + \epsilon) c_n$  is also convergent series.

$\therefore$  By comparison test  $\sum a_n$  is convergent.

(ii) Let  $\lim_{n \rightarrow \infty} \left(\frac{a_n}{c_n}\right) = k > 0$

Choose  $\epsilon = \frac{1}{2}k$ . Then there exists  $n_1 \in \mathbf{N}$  such that  $k - \frac{1}{2}k < \frac{a_n}{c_n} < k + \frac{1}{2}k$  for all  $n \geq n_1$ .

$\therefore \frac{a_n}{c_n} > \frac{1}{2}k$  for all  $n \geq n_1$

$\therefore a_n > \frac{1}{2}k c_n$  for all  $n \geq n_1$

Since  $c_n$  is a divergent series,  $\sum \frac{1}{2}k c_n$  is also divergent series.

$\therefore$  By comparison test,  $\sum a_n$  diverges.

#### Theorem: 4.6

i) Let  $\sum c_n$  be a convergent series of positive terms. Let  $\sum a_n$  be another series of positive terms. If there exists  $m \in \mathbf{N}$  such that  $\frac{a_{n+1}}{a_n} \leq \frac{c_{n+1}}{c_n}$  for all  $n \geq m$ , then  $\sum a_n$  is convergent.

ii) Let  $\sum d_n$  be a divergent series of positive terms. Let  $\sum a_n$  be another series of positive terms. If there exists  $m \in \mathbf{N}$  such that

$$\frac{a_{n+1}}{a_n} \geq \frac{d_{n+1}}{d_n} \quad \text{for all } n \geq m, \text{ then } \sum a_n \text{ is divergent.}$$

**Proof.**(i)

$$\frac{a_{n+1}}{a_n} \leq \frac{a_n}{c_n}$$

$\therefore (\frac{a_n}{c_n})$  is a monotonic decreasing sequence.

$$\therefore \frac{a_n}{c_n} \leq k \text{ for all } n \text{ where } k = \frac{a_1}{c_1} \therefore a_n \leq kc_n \text{ for all } n \in \mathbf{N}.$$

Now,  $\sum c_n$  is convergent. Hence  $\sum kc_n$  is also a convergent series of positive terms.

$\therefore \sum a_n$  is also convergent

(ii) Proof is similar to that of (i).

### **Theorem :4.7**

The harmonic series  $\sum \frac{1}{n^p}$  converges if  $p > 1$  and if  $p \leq 1$ .

**Proof.**

Case (i) Let  $p=1$ .

Then the series becomes  $\sum (1/n)$  which diverges.

Case (ii) Let  $p < 1$ .

Then  $n^p < n$  for all  $n$ .

$$\therefore \frac{1}{n^p} > \frac{1}{n} \text{ for all } n$$

$\therefore$  By comparison test  $\sum \frac{1}{n^p}$  diverges.

Case (iii) Let  $p > 1$ .

$$\text{Let } s_n = 1 + \frac{1}{2^p} + \frac{1}{3^p} + \dots + \frac{1}{n^p}$$

$$\text{Then } s_{2^{n+1}-1} = 1 + \frac{1}{2^p} + \dots + \frac{1}{(2^{n+1}-1)^p}$$

$$= 1 + \left(\frac{1}{2^p} + \frac{1}{3^p}\right) + \left(\frac{1}{4^p} + \frac{1}{5^p} + \frac{1}{6^p} + \frac{1}{7^p}\right) + \dots + \left(\frac{1}{(2^n)^p} + \frac{1}{(2^{n+1})^p} + \dots + \frac{1}{(2^{n+1}-1)^p}\right)$$

$$< 1 + 2\left(\frac{1}{2^p}\right) + 4\left(\frac{1}{4^p}\right) + \dots + 2^n\left(\frac{1}{(2^n)^p}\right)$$

$$= 1 + \frac{1}{2^{p-1}} + \frac{1}{2^{2p-2}} + \frac{1}{2^{(p-1)n}}$$

$$\therefore s_{2^{n+1}-1} < 1 + \frac{1}{2^{p-1}} + \left(\frac{1}{2^{p-1}}\right)^2 + \dots + \left(\frac{1}{2^{p-1}}\right)^n$$

Now, since  $p > 1$ ,  $p-1 > 0$

Hence

$$\frac{1}{2^{p-1}} < 1$$

Therefore  $1 + \frac{1}{2^{p-1}} + \left(\frac{1}{2^{p-1}}\right)^2 + \dots + \left(\frac{1}{2^{p-1}}\right)^n < \frac{1}{1 - \frac{1}{2^{p-1}}} = k(\text{say})$

$$\therefore s_{2^{n+1}-1} < k$$

Now let  $n$  be any positive integer. Choose  $m \in \mathbb{N}$  such that  $n \leq 2^{m+1} - 1$ . Since  $(s_n)$  is a monotonic increasing sequence,  $s_n \leq s_{2^{m+1}-1}$ .

Hence  $s_n < k$  for all  $n$ .

Thus  $(s_n)$  is a monotonic increasing sequence and is bounded above.

$\therefore (s_n)$  is convergent.

$\therefore \sum \frac{1}{n^p}$  is convergent.

### Solved problems.

1. Discuss the convergence of the series  $\sum \frac{1}{\sqrt{(n^3+1)}}$

**Solution.**

$$\frac{1}{\sqrt{(n^3+1)}} < \frac{1}{n^{\frac{3}{2}}}$$

Also  $\sum \frac{1}{n^{\frac{3}{2}}}$  is convergent

$\therefore$  By comparison test,  $\sum \frac{1}{\sqrt{(n^3+1)}}$  is convergent.

2. Discuss the convergence of the series  $\sum_3^{\infty} (\log \log n)^{-\log n}$ .

**Solution.**

Let  $a_n = (\log \log n)^{-\log n}$

$\therefore a_n = n^{-\theta_n}$  where  $\theta_n = \log(\log \log n)$ .

Since  $\lim_{n \rightarrow \infty} \log \log \log n = \infty$ , there exists  $m \in \mathbb{N}$  such that  $\theta_n \geq 2$  for all  $n \geq m$ .

$\therefore n^{-\theta} \leq n^{-2}$  for all  $n \geq m$ .

$\therefore a_n \leq n^{-2}$  for all  $n \geq m$ .

Also  $\sum n^{-2}$  is convergent.

$\therefore$  By comparison test the given series is convergent.

Show that  $\sum \frac{1}{4n^2-1} = \frac{1}{2}$

**Solution.**

Let  $a_n = \frac{1}{4n^2-1}$

Clearly  $a_n < \frac{1}{n^2}$  Also  $\sum \frac{1}{n^2}$  is convergent

$\therefore$  by comparison test, the given series converges

Now,  $a_n = \frac{1}{4n^2-1} = \frac{1}{2} \left[ \frac{1}{2n-1} - \frac{1}{2n+1} \right]$  (by partial fraction)

$$\therefore S_n = a_1 + a_2 + \dots + a_n$$

$$= \frac{1}{2} \left[ \left( \frac{1}{1} - \frac{1}{3} \right) + \left( \frac{1}{3} - \frac{1}{5} \right) + \dots + \left( \frac{1}{2n-1} - \frac{1}{2n+1} \right) \right]$$

$$= \frac{1}{2} \left[ \left( 1 - \frac{1}{2n+1} \right) \right]$$

$$\therefore \lim_{n \rightarrow \infty} S_n = \frac{1}{2}$$

$$\text{Hence } \sum \frac{1}{4n^2-1} = \frac{1}{2}$$

**Theorem 4.8 (Kummer's test)**

Let  $\sum a_n$  be a given series of positive terms and  $\sum \frac{1}{d_n}$  be a series of a positive terms diverging to  $\infty$ . Then

- (i)  $\sum a_n$  converges if  $\lim_{n \rightarrow \infty} (d_n \frac{a_n}{a_{n+1}} - d_{n+1}) > 0$  and
- (ii)  $\sum a_n$  diverges if  $\lim_{n \rightarrow \infty} (d_n \frac{a_n}{a_{n+1}} - d_{n+1}) < 0$ .

**Proof.**

(i) Let  $\lim_{n \rightarrow \infty} (d_n \frac{a_n}{a_{n+1}} - d_{n+1}) = l > 0$ .

We distinguish two cases.

Case (i)  $l$  is finite.

Then given  $\epsilon > 0$ , there exists  $m \in \mathbf{N}$  such that

$$l - \epsilon < d_n \frac{a_n}{a_{n+1}} - d_{n+1} < l + \epsilon \text{ for all } n \geq m$$

$$\therefore d_n a_n - d_{n+1} a_{n+1} > (l - \epsilon) a_{n+1} \text{ for all } n \geq m.$$

Taking  $\epsilon = (1/2)l$ , we get  $d_n a_n - d_{n+1} a_{n+1} > (1/2)l a_{n+1}$  for all  $n \geq m$ .

Now, let  $n \geq m$

$$\therefore d_m a_m - d_{m+1} a_{m+1} > (1/2) l a_{m+1}$$

$$d_{m+1} a_{m+1} - d_{m+2} a_{m+2} > (1/2) l a_{m+2}$$

.....

.....

$$d_{n-1} a_{n-1} - d_n a_n > (1/2) l a_n$$

Adding, we get

$$d_m a_m - d_n a_n > (1/2) l (a_{m+1} + \dots + a_n)$$

$$d_m a_m - d_n a_n > (1/2) l (s_n - s_m) \quad \text{where } s_n = a_1 + a_2 + \dots + a_n$$

$$d_m a_m > (1/2) l (s_n - s_m)$$

$$s_n < \frac{2d_m a_m + l s_m}{l} \text{ which is independent of } n$$

∴ The sequence  $(s_n)$  of partial sums is bounded.

∴  $a_n$  is convergent.

Case (ii)  $l = \infty$ .

Then given real number  $k > 0$  there exists a positive integer  $m$  such that  $d_n \frac{a_n}{a_{n+1}} - d_{n+1} > k$

for all  $n \geq m$ .

$$\therefore d_n a_n - d_{n+1} a_{n+1} > k a_{n+1} \text{ for all } n \geq m.$$

Now, let  $n \geq m$ . Writing the above inequality for  $m, m+1, \dots, (n-1)$  and adding we get

$$d_m a_m - d_n a_n > k (a_{m+1} + \dots + a_n)$$

$$= k (s_n - s_m).$$

$$\therefore d_m a_m > k (s_n - s_m).$$

$$\therefore s_n < \frac{d_m a_m}{k} + s_m$$

∴ The sequence  $(s_n)$  is bounded and hence  $\sum a_n$  is convergent.

$$(ii) \lim_{n \rightarrow \infty} (d_n \frac{a_n}{a_{n+1}} - d_{n+1}) = l < 0$$

Suppose  $l$  is finite.

Choose  $\epsilon > 0$  such that  $l + \epsilon < 0$ . Then there exists  $m \in \mathbf{N}$  such that

$$l + \epsilon < d_n \frac{a_n}{a_{n+1}} - d_{n+1} < l + \epsilon < 0 \text{ for all } n \geq m.$$

$$\therefore d_n a_n < d_{n+1} a_{n+1} \text{ for all } n \geq m.$$

Now let  $n \geq m$

$$\therefore d_m a_m < d_{m+1} a_{m+1}$$

.....  
 .....

$$d_{n-1} a_{n-1} < d_n a_n$$

$$\therefore d_m a_m < d_n a_n.$$

$$\therefore a_n > \frac{d_m a_m}{d_n} \text{ Also by hypothesis } \sum \frac{1}{d_n} \text{ is divergent}$$

Hence  $\sum_{n=1}^{\infty} \frac{d_m a_m}{d_n}$  is divergent.

∴ By comparison test  $\sum a_n$  is divergent.

The proof is similar if  $l = -\infty$ .

**Corollary 1.(D' Alembert's ratio test)**

Let  $\sum a_n$  be a series of positive terms. Then  $\sum a_n$  converges if  $\lim_{n \rightarrow \infty} \frac{a_n}{a_{n+1}} > 1$  and diverges

$$\lim_{n \rightarrow \infty} \frac{a_n}{a_{n+1}} < 1.$$

**Proof.**

The series  $1 + 1 + 1 + \dots$  is divergent  
 $\therefore$  We can put  $d_n = 1$  in Kummer's test.

$$\text{Then } d_n \frac{a_n}{a_{n+1}} - d_{n+1} = \frac{a_n}{a_{n+1}} - 1$$

Hence  $\sum a_n$  converges if  $\lim_{n \rightarrow \infty} \left( \frac{a_n}{a_{n+1}} - 1 \right) > 0$

Therefore  $\sum a_n$  converges if  $\lim_{n \rightarrow \infty} \frac{a_n}{a_{n+1}} > 1$

Similarly  $\sum a_n$  diverges if  $\lim_{n \rightarrow \infty} \frac{a_n}{a_{n+1}} < 1$ .

### Corollary 2. (Raabe's test)

Let  $\sum a_n$  be a series of positive terms. Then  $\sum a_n$  converges if  $\lim_{n \rightarrow \infty} n \left( \frac{a_n}{a_{n+1}} - 1 \right) > 1$  and diverges if  $\lim_{n \rightarrow \infty} n \left( \frac{a_n}{a_{n+1}} - 1 \right) < 1$ .

**Proof.** The series  $\sum \frac{1}{n}$  is divergent.

$\therefore$  We can put  $d_n = n$  in Kummer's test.

$$\begin{aligned} \text{Then } d_n \frac{a_n}{a_{n+1}} - d_{n+1} &= n \frac{a_n}{a_{n+1}} - (n+1) \\ &= n \left( \frac{a_n}{a_{n+1}} - 1 \right) - 1 \end{aligned}$$

$\therefore \sum a_n$  converges if  $\lim_{n \rightarrow \infty} n \left( \frac{a_n}{a_{n+1}} - 1 \right) > 1$  and diverges if  $\lim_{n \rightarrow \infty} n \left( \frac{a_n}{a_{n+1}} - 1 \right) < 1$

### Theorem: 4.9 (Gauss's test)

Let  $\sum a_n$  be a series of positive terms such that  $\frac{a_n}{a_{n+1}} = 1 + \frac{\beta}{n} + \frac{r_n}{n^p}$  where  $p > 1$  and  $(r_n)$  is a bounded

sequence. Then the series  $\sum a_n$  converges if  $\beta > 1$  and diverges if  $\beta \leq 1$ .

**Proof:**

$$\frac{a_n}{a_{n+1}} = 1 + \frac{\beta}{n} + \frac{r_n}{n^p}, \quad p > 1$$

$$n \left( \frac{a_n}{a_{n+1}} - 1 \right) = n \left( \frac{\beta}{n} + \frac{r_n}{n^p} \right) = \beta + \frac{r_n}{n^{p-1}}$$

Now, since  $p > 1$ ,  $\lim_{n \rightarrow \infty} \frac{1}{n^{p-1}} = 0$

Also  $(r_n)$  is a bounded sequence.

$$\text{Hence } \lim_{n \rightarrow \infty} \frac{r_n}{n^{p-1}} = 0$$

$$\therefore \lim_{n \rightarrow \infty} n \left( \frac{a_n}{a_{n+1}} - 1 \right) = \beta$$

$\therefore$  By Raabe's test  $\sum a_n$  converges if  $\beta > 1$  and  $\sum a_n$  diverges if  $\beta < 1$ .

If  $\beta = 1$ , Raabe's test fails. In this case we apply Kummer's test by taking  $d_n = n \log n$

$$\begin{aligned} \text{Now, } d_n \frac{a_n}{a_{n+1}} - d_{n+1} &= n \log n \left( 1 + \frac{1}{n} + \frac{r_n}{n^p} \right) - (n+1) \log(n+1) \\ &= -(n+1) \log \left( 1 + \frac{1}{n} \right) + \frac{r_n \log n}{n^{p-1}} \\ &= -\log \left( 1 + \frac{1}{n} \right)^{n+1} + \frac{r_n \log n}{n^{p-1}} \end{aligned}$$

Now, by hypothesis  $(r_n)$  is a bounded sequence and  $\left( \frac{\log n}{n^{p-1}} \right) \rightarrow 0$

$$\therefore \left( \frac{r_n \log n}{n^{p-1}} \right) \rightarrow 0$$

$$\lim_{n \rightarrow \infty} \left( d_n \frac{a_n}{a_{n+1}} - d_{n+1} \right) = -\log e = -1 < 0$$

Hence by Kummer's test  $\sum a_n$  diverges

### **Solved problems.**

1. Test the convergence of the series  $\frac{1}{3} + \frac{1.2}{3.5} + \frac{1.2.3}{3.5.7} + \dots$

**Solution:**

$$\text{Let } a_n = \frac{1.2.3 \dots n}{3.5.7 \dots (2n+1)}$$

$$\frac{a_n}{a_{n+1}} = \frac{2n+3}{n+1} \cdot \frac{2+\frac{3}{n}}{1+\frac{1}{n}}$$

$$\lim_{n \rightarrow \infty} \frac{a_n}{a_{n+1}} = 2 > 1$$

Therefore by D' Alembert's ratio test  $\sum a_n$  is convergent.

### **Theorem 4.10 (Cauchy's root test)**

Let  $\sum a_n$  be a series of positive terms. Then  $\sum a_n$  is convergent if  $\lim_{n \rightarrow \infty} a_n^{1/n} < 1$  and divergent if  $\lim_{n \rightarrow \infty} a_n^{1/n} > 1$ .

**Proof.**

**Case(i)** let  $\lim_{n \rightarrow \infty} a_n^{1/n} = l < 1$ .

Choose  $\epsilon > 0$  such that  $l + \epsilon < 1$ .

Then there exists  $m \in \mathbb{N}$  such that  $a_n^{1/n} < l + \epsilon$  for all  $n \geq m$

$$\therefore a_n < (l + \epsilon)^n \text{ for all } n \geq m.$$

Now since  $l + \epsilon < 1$ ,  $\sum (l + \epsilon)^n$  is convergent.

$\therefore$  By comparison test  $\sum a_n$  is convergent.

**Case (ii)** Let  $\lim_{n \rightarrow \infty} a_n^{1/n} = l > 1$ .

Choose  $\epsilon > 0$  such that  $l - \epsilon > 1$ .

Then there exists  $m \in \mathbf{N}$  such that  $a_n^{1/n} > l - \epsilon$  for all  $n \geq m$

$\therefore a_n > (l - \epsilon)^n$  for all  $n \geq m$ .

Now, since  $l - \epsilon > 1$ ,  $\sum (l - \epsilon)^n$  is divergent

$\therefore$  By comparison test,  $\sum a_n$  is divergent.

**Problems:**

1. Test the convergence of  $\sum \frac{1}{(\log n)^n}$

**Solution:**

$$\text{Let } a_n = \frac{1}{(\log n)^n}$$

$$\sqrt[n]{a_n} = \frac{1}{\log n}$$

$$\lim_{n \rightarrow \infty} \sqrt[n]{a_n} = 0 < 1$$

$\therefore$  by Cauchy's root test  $\sum \frac{1}{(\log n)^n}$  converges.

2. Prove that the series  $\sum e^{-\sqrt{n}} x^n$  converges if  $0 < x < 1$  and diverges if  $x > 1$ .

**Solution:**

$$\text{Let } a_n = e^{-\sqrt{n}} x^n$$

$$a_n^{1/n} = (e^{-\sqrt{n}} x^n)^{1/n}$$

$$\lim_{n \rightarrow \infty} a_n^{1/n} = x$$

Hence by Cauchy's root test the given series converges if  $0 < x < 1$  and diverges if  $x > 1$ .

## UNIT - V

### ALTERNATIVE SERIES

**Definition:** A series whose terms are alternatively positive and negative is called an alternating series.

Thus an alternating series is of the form

$$a_1 - a_2 + a_3 - a_4 + \dots = \sum (-1)^{n+1} a_n \text{ where } a_n > 0 \text{ for all } n.$$

**For example**

i)  $1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \dots = \sum (-1)^{n+1} \left(\frac{1}{n}\right)$  is an alternating series.

ii)  $2 - \frac{3}{2} + \frac{4}{3} - \frac{5}{4} + \dots = \sum (-1)^{n+1} \left(\frac{n+1}{n}\right)$  is an alternating series.

We now prove a test for convergence of an alternating series.

**Theorem :5.1( Leibnitz's test )**

Let  $\sum (-1)^{n+1} a_n$  be an alternating series whose terms an satisfy the following conditions

i)  $(a_n)$  is a monotonic decreasing sequence.

ii)  $\lim_{n \rightarrow \infty} a_n = 0$ .

Then the given alternating series converges.

**Proof:**

Let  $(s_n)$  denote the sequence of partial sums of the given series.

Then  $s_{2n} = a_1 - a_2 + a_3 - a_4 + \dots + a_{2n-1} - a_{2n}$

$s_{2n+2} = s_{2n} + a_{2n+1} - a_{2n+2}$

Therefore,  $s_{2n+2} - s_{2n} = (a_{2n+1} - a_{2n+2}) \geq 0$  ( by (i)).

Therefore,  $s_{2n+2} \geq s_{2n}$ .

Therefore,  $(s_{2n})$  is a monotonic increasing sequence.

Also,  $s_{2n} = a_1 - (a_2 - a_3) - (a_4 - a_5) - \dots - (a_{2n-2} - a_{2n-1}) - a_{2n}$   
 $\leq a_1$  ( by (i)).

Therefore,  $(s_{2n})$  is bounded above.

Therefore,  $(s_{2n})$  is a convergent sequence.

Let  $(s_{2n}) \rightarrow s$ .

Now,  $s_{2n+1} = s_{2n} + a_{2n+1}$ .

Therefore,  $\lim_{n \rightarrow \infty} s_{2n+1} = \lim_{n \rightarrow \infty} s_{2n} + \lim_{n \rightarrow \infty} a_{2n+1} = s + 0 = s$  ( by (i))

Therefore,  $(s_{2n+1}) \rightarrow s$ .

Thus the subsequences  $(s_{2n})$  and  $(s_{2n+1})$  converges to the same limits.

Therefore,  $(s_n) \rightarrow s$  ( by theorem 3.29).

Therefore, The given series converges.

**Problem : 1** Show that the series  $1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \dots$  converges.

**Solution :** The given series is  $\sum (-1)^{n+1} a_n$  where  $a_n = \frac{1}{n}$ . Clearly  $a_n > a_{n+1}$  for all n and hence  $(a_n)$  is monotonic decreasing.

Also  $\lim_{n \rightarrow \infty} a_n = \lim_{n \rightarrow \infty} \frac{1}{n} = 0$ .

∴ By Leibnitz's test the given series converges.

**Problem : 2** Show that the series  $\sum \frac{(-1)^{n+1}}{\log(n+1)}$  converges.

**Solution :** Let  $a_n = \frac{1}{\log(n+1)}$ .

Clearly  $(a_n) \rightarrow 0$  as  $n \rightarrow \infty$ .

Also  $\frac{1}{\log n} > \frac{1}{\log(n+1)}$  for all  $n \geq 2$ .

$\therefore$  By Leibnitz's test the given series converges.

**Absolute convergence**

**Definition :** A series  $\sum a_n$  is said to be **absolutely convergent** if the series  $\sum |a_n|$  is convergent.

**Example :** The series  $\sum \frac{(-1)^n}{n^2}$  is absolutely convergent, for  $\sum \left| \frac{(-1)^n}{n^2} \right| = \sum \frac{1}{n^2}$  which is convergent.

**Theorem: 5.2**

Any absolutely convergent series is convergent.

**Proof :**

Let  $\sum a_n$  be absolutely convergent.

$\therefore \sum |a_n|$  is convergent.

Let  $s_n = a_1 + a_2 + a_3 + a_4 + \dots + a_n$  and  $t_n = |a_1| + |a_2| + \dots + |a_n|$

By hypothesis  $(t_n)$  is convergent and hence is a Cauchy sequence

Hence given  $\epsilon > 0$ , there exist  $n_1 \in \mathbb{N}$  such that  $|t_n - t_m| < \epsilon$  for all  $n, m > n_1$  .....  
(1)

Now let  $m > n$ .

Then  $|s_n - s_m| = |a_{n+1} + a_{n+2} + \dots + a_m|$

$\leq |a_{n+1}| + |a_{n+2}| + \dots + |a_m|$

$= |t_n - t_m| < \epsilon$  for all  $n, m > n_1$  (by (i)).

$\therefore (s_n)$  is a Cauchy sequence in  $\mathbb{R}$  and hence is convergent

$\therefore \sum a_n$  is a convergent series.

**Definition :** A series  $\sum a_n$  is said to be conditionally convergent if it is convergent but not absolutely convergent.

**Example :** The series  $\sum \frac{(-1)^n}{n^2}$  is conditionally convergent.

**Theorem: 5.3**

In a absolutely convergent series, the series formed by its positive terms alone is convergent and the series formed by its negative terms alone is convergent and conversely.

**Proof :**

Let  $\sum a_n$  be the given absolutely convergent series.

We define  $p_n = \begin{cases} a_n & \text{if } a_n > 0 \\ 0 & \text{if } a_n \leq 0 \end{cases}$  and  $q_n = \begin{cases} 0 & \text{if } a_n \geq 0 \\ -a_n & \text{if } a_n < 0 \end{cases}$

(i.e)  $p_n$  is a positive terms of the given series and  $q_n$  is the modulus of a negative term.

$\sum p_n$  is the series formed with the positive terms of the given series and  $q_n$  is the series formed with the moduli of the negative terms of the given series.

Clearly  $p_n \leq |a_n|$  and  $q_n \leq |a_n|$  for all  $n$ .

Since the given series is absolutely convergent,  $\sum |a_n|$  is a convergent series of positive terms. Hence by comparison test  $\sum p_n$  and  $\sum q_n$  are convergent.

Conversely  $\sum p_n$  and  $\sum q_n$  are convergent to  $p$  and  $q$  respectively. We claim that  $\sum a_n$  is absolutely convergent.

We have  $|a_n| = p_n + q_n$

$$\therefore \sum |a_n| = \sum (p_n + q_n)$$

$$= \sum p_n + \sum q_n$$

$$= p + q.$$

$\therefore \sum a_n$  is absolutely convergent

#### Theorem: 5.4

If  $\sum a_n$  is an absolutely convergent series and  $(b_n)$  is a bounded sequence, then the series  $\sum a_n b_n$  is an absolutely convergent series.

**Proof :**

since  $(b_n)$  is a bounded series, there exist a real number  $k > 0$  such that  $|b_n| \leq k$  for all  $n$ .

$$|a_n b_n| = |a_n| |b_n|$$

$$\leq k |a_n| \text{ for all } n.$$

Since  $\sum a_n$  is absolutely convergent  $\sum |a_n|$  is convergent.

$\therefore \sum k |a_n|$  is convergent.

$\therefore$  By comparison test,  $\sum |a_n b_n|$  is convergent.

$\therefore \sum a_n b_n$  is an absolutely convergent.

**Problem 1 :** Test the convergence of  $\sum \frac{(-1)^n \sin n\alpha}{n^3}$

**Solution :** We have  $\left| \frac{(-1)^n \sin n\alpha}{n^3} \right| \leq \frac{1}{n^3}$  (since,  $|\sin \theta| \leq 1$ )

$\therefore$  By comparison test the series is absolutely convergent.

#### Tests For Convergence of Series Of Arbitrary Terms

##### Theorem: 5.5

Let  $(a_n)$  be a bounded sequence and  $(b_n)$  be a monotonic decreasing bounded sequence. Then the series  $\sum a_n (b_n - b_{n+1})$  is absolutely convergent.

**Proof:**

Since  $(a_n)$  and  $(b_n)$  are bounded sequences there exists a real number  $k > 0$  such that  $|a_n| \leq k$  and

$$|b_n| \leq k \text{ for all } n.$$

Let  $s_n$  denote the partial sum of the series  $\sum |a_n (b_n - b_{n+1})|$

$$\therefore s_n = \sum_{r=1}^n |a_r (b_r - b_{r+1})|$$

$$= \sum_{r=1}^n |a_r| (b_r - b_{r+1})$$

$$\leq k \sum_{r=1}^n (b_r - b_{r+1})$$

$$= k (b_1 - b_{n+1})$$

$$\leq k (|b_1| + |b_{n+1}|)$$

$$\leq k (k + k) = 2k^2$$

$\therefore (s_n)$  is a bounded sequence.

$\therefore \sum |a_n (b_n - b_{n+1})|$  is convergent.

Hence  $\sum a_n (b_n - b_{n+1})$  is absolutely convergent.

**Theorem: 5.6 (Dirichlet's test)**

Let  $\sum a_n$  be a series whose sequence of partial sums  $(s_n)$  is bounded. Let  $(b_n)$  be a monotonic decreasing sequence converging to 0. Then the series  $\sum a_n b_n$  converges.

**Proof:**

Let  $t_n$  denote the partial sum of the series  $\sum a_n b_n$

$$\therefore t_n = \sum_{r=1}^n a_r b_r$$

$$= s_1 b_1 + \sum_{r=2}^n (s_r - s_{r-1}) b_r \quad (\text{Since } s_r - s_{r-1} = a_r)$$

$$= \sum_{r=1}^{n-1} (b_r - b_{r+1}) s_r + s_n b_n \dots \dots \dots (1)$$

Since  $(s_n)$  is bounded and  $(b_n)$  is a monotonic decreasing bounded sequence  $\sum_{r=1}^{n-1} (b_r - b_{r+1}) s_r$

is a convergent sequence.

Also since  $(s_n)$  is bounded and  $(b_n) \rightarrow 0, (s_n b_n) \rightarrow 0$

From (1) it follows that  $(t_n)$  is convergent.

Hence  $\sum a_n b_n$  converges.

**Theorem: 5.7 (Abel's test)**

Let  $\sum a_n$  be a convergent series. Let  $(b_n)$  be a bounded monotonic sequence. Then  $\sum a_n b_n$  is convergent.

**Proof:**

Since  $(b_n)$  be a bounded monotonic sequence,  $(b_n) \rightarrow b$  (say)

$$\text{Let } c_n = \begin{cases} b - b_n & \text{if } (b_n) \text{ is monotonic increasing} \\ b_n - b & \text{if } (b_n) \text{ is monotonic decreasing} \end{cases}$$

$$\therefore a_n c_n = \begin{cases} a_n b - a_n b_n & \text{if } (b_n) \text{ is monotonic increasing} \\ a_n b_n - a_n b & \text{if } (b_n) \text{ is monotonic decreasing} \end{cases}$$

$$\therefore a_n b_n = \begin{cases} b a_n - a_n c_n & \text{if } (b_n) \text{ is monotonic increasing} \\ b a_n + a_n c_n & \text{if } (b_n) \text{ is monotonic decreasing} \end{cases} \dots \dots \dots (1)$$

Clearly  $(c_n)$  is a monotonic decreasing sequence converging to 0. Also since  $\sum a_n$  is a convergent series its sequence of partial sums is bounded.

$\therefore$  by Dirichlet's test  $\sum a_n c_n$  is convergent.

Also  $\sum a_n$  is convergent.

$\sum b_n$  is convergent.

Hence by (1)  $\sum a_n b_n$  is convergent.

**Problems:**

1. Show that convergence of  $\sum a_n$  implies the convergence of  $\sum \frac{a_n}{n}$

**Solution:**

Let  $\sum a_n$  be convergent

The sequence  $(1/n)$  is a bounded monotonic sequence.

Hence by Abel's test  $\sum \frac{a_n}{n}$  is convergent. 2. Prove that  $\sum_{n=2}^{\infty} \frac{\sin n}{\log n}$  is convergent.

**Solution:**

Let  $a_n = \sin n$  and  $b_n = 1/\log n$ .

Clearly  $(b_n)$  is a monotonic decreasing sequence converging to 0.

$$s_n = \sin 2 + \sin 3 + \dots + \sin (n+1)$$

$$= \frac{1}{2} \operatorname{cosec} \frac{1}{2} \left[ \cos \left( \frac{3}{2} \right) - \cos \left( \frac{2n+1}{2} \right) \right]$$

$$\therefore |s_n| \leq \operatorname{cosec} \left( \frac{1}{2} \right)$$

$(s_n)$  is a bounded sequence.

Hence by Dirichlet's test  $\sum_{n=2}^{\infty} \frac{\sin n}{\log n}$  is convergent

**Exercise:**

1. Show that the series  $\sum \frac{\sin n\theta}{n}$  converges for all values of  $\theta$  and  $\sum \frac{\cos n\theta}{n}$  converges if  $\theta$  is not a multiple of  $2\pi$ .

**MULTIPLICATION OF SERIES**

**Definition :** Let  $\sum a_n$  and  $\sum b_n$  be two series.

$$\text{Let } c_1 = a_1 b_1$$

$$c_2 = a_1 b_2 + a_2 b_1$$

$$c_3 = a_1 b_3 + a_2 b_2 + a_3 b_1$$

.....

.....

.....

$$c_n = a_1 b_n + a_2 b_{n-1} + a_3 b_{n-2} + \dots + a_n b_1.$$

.....

.....

.....

Then the series  $\sum c_n$  is called the Cauchy product of  $\sum a_n$  and  $\sum b_n$ .

**Example :**

$$\text{Consider the series } \sum \frac{(-1)^{n-1}}{(\sqrt{n})}$$

We take the Cauchy product of the series with itself.

Let  $a_n = \frac{(-1)^{n-1}}{(\sqrt{n})} = b_n$ .

Then  $c_n = a_1b_n + a_2b_{n-1} + a_3b_{n-2} + \dots + a_nb_1$ .

$$= (-1)^{n-1} \left[ \frac{1}{\sqrt{n}} + \frac{1}{\sqrt{2}\sqrt{n-1}} + \frac{1}{\sqrt{3}\sqrt{n-2}} + \dots + \frac{1}{\sqrt{n}} \right]$$

$$\therefore |c_n| \geq \left[ \frac{1}{\sqrt{n}\sqrt{n}} + \frac{1}{\sqrt{n}\sqrt{n}} + \dots + \frac{1}{\sqrt{n}\sqrt{n}} \right]$$

$$= n \frac{1}{n} = 1.$$

$\therefore |c_n| \geq 1$  for all  $n \in \mathbb{N}$ .

$\therefore$  The Cauchy product  $\sum c_n$  is divergent.

However the given series  $\sum \frac{(-1)^{n-1}}{(\sqrt{n})}$  converges ( by Leibnitz's test ).

Thus the Cauchy product of two convergent series need not converges.

**Theorem: 5.8 (Abel's theorem).**

If  $\sum a_n$  and  $\sum b_n$  converge to  $a$  and  $b$  respectively and if the Cauchy product  $\sum c_n$  converges to  $c$ , then  $c = ab$ .

**Proof:**

Let  $A_n = a_1+a_2+\dots + a_n$ .

$B_n = b_1+b_2+\dots + b_n$ .

$C_n = c_1+c_2+\dots +c_n$ .

$$\begin{aligned} \therefore C_n &= a_1b_1 + (a_1b_2 + a_2b_1) + \dots + (a_1b_n + a_2b_{n-1} + \dots + a_nb_1) \\ &= a_1(b_1 + b_2 + \dots + b_n) + a_2(b_1 + b_2 + \dots + b_{n-1}) + \dots + a_nb_1 \\ &= a_1B_n + a_2B_{n-1} + \dots + a_nB_1 \end{aligned} \tag{1}$$

From (1)  $C_1 = a_1B_1$

$C_2 = a_1B_1 + a_2B_1$

.....

.....

$C_n = a_1B_n + a_2B_{n-1} + \dots + a_nB_1$

$\therefore C_1 + C_2 + \dots + C_n$

$= a_1B_1 + (a_1B_1 + a_2B_1) + \dots + (a_1B_1 + a_2B_2 + \dots + a_nB_n)$

$= B_1(a_1+a_2+\dots + a_n) + B_2(a_1+a_2+\dots + a_{n-1}) + \dots + B_na_1$

$= A_n B_1 + A_{n-1} B_2 + \dots + A_1 B_n$ .

By hypothesis  $\sum a_n$  converges to  $a$  and  $\sum b_n$  converges to  $b$ .

$\therefore (A_n) \rightarrow a$  and  $(B_n) \rightarrow b$ .

Hence by Cesaro's theorem,

$$\left( \frac{A_1 B_n + A_2 B_{n-1} + \dots + A_n B_1}{n} \right) \rightarrow ab.$$

i.e.,  $\left( \frac{C_1 + C_2 + \dots + C_n}{n} \right) \rightarrow ab.$

Also by hypothesis  $\sum c_n$  converges to  $c$

$\therefore (C_n) \rightarrow c$ .

Hence by Cauchy's first limit theorem,

$$\left( \frac{c_1 + c_2 + \dots + c_n}{n} \right) \rightarrow c$$

$\therefore c = ab$ .

**Theorem 5.9 (Merten's Theorem)**

If the series  $\sum a_n$  and  $\sum b_n$  converge to the sums  $a$  and  $b$  respectively and if one of the series, say,  $\sum a_n$  is absolutely convergent, then the Cauchy product  $\sum C_n$  converges to the sum  $ab$ .

**Proof :**

Let  $A_n = a_1 + a_2 + \dots + a_n$ .

$B_n = b_1 + b_2 + \dots + b_n$ .

$C_n = c_1 + c_2 + \dots + c_n$ .

$\overline{A_n} = |a_1| + \dots + |a_n|$

and  $\sum |a_n| = \overline{a}$ , so that  $(\overline{A_n}) \rightarrow \overline{a}$ .

Now, let  $B_n = b + r_n$ .

Since,  $(B_n) \rightarrow b$ ,  $(r_n) \rightarrow 0$  as  $n \rightarrow \infty$ .

$$\begin{aligned} \text{Now, } C_n &= a_1 B_n + a_2 B_{n-1} + \dots + a_n B_1 \\ &= a_1(b + r_n) + a_2(b + r_{n-1}) + \dots + a_n(b + r_1) \\ &= (a_1 + \dots + a_n)b + (a_1 r_n + \dots + a_n r_1) \\ &= A_n b + (a_1 r_n + \dots + a_n r_1) \\ &= A_n b + R_n \quad \text{where } R_n = a_1 r_n + \dots + a_n r_1. \end{aligned}$$

Since,  $(A_n) \rightarrow a$ ,  $(A_n b) \rightarrow ab$ .

$\therefore$  To prove that  $(C_n) \rightarrow a b$ , it is enough if we prove that  $(R_n) \rightarrow 0$

Let  $\varepsilon > 0$  be given. Since  $(r_n) \rightarrow 0$ , there exist  $n_1 \in \mathbb{N}$  such that  $|r_n| < \varepsilon$  for all  $n \geq n_1$ .

.....(1) Also since the sequence  $(r_n)$  is convergent, it is a bounded sequences and

hence there exists  $k \geq 0$  such that  $|r_n| < k$  for all  $n$ . .....

(2)

Further since  $(\overline{A_n}) \rightarrow \overline{a}$ ,  $(\overline{A_n})$  is a Cauchy sequence.

$\therefore$  There exists  $n_2 \in \mathbb{N}$  such that  $|\overline{A_n} - \overline{A_m}| < \varepsilon$  for all  $n, m \geq n_2$ .....(3)

Let  $p = \max \{n_1, n_2\}$ ,

Let  $n \geq 2p$ .

Then  $R_n = a_1 r_n + a_2 r_{n-1} + \dots + a_p r_{n-p+1} + a_{p+1} r_{n-p} + \dots + a_n r_1$ .

$$\therefore |R_n| \leq \{ |a_1| |r_n| + |a_2| |r_{n-1}| + \dots + |a_p| |r_{n-p+1}| \} + \{ |a_{p+1}| |r_{n-p}| + \dots + |a_n| |r_1| \}$$

Now  $n \geq 2p \Rightarrow n, n-1, \dots, (n-p-1) \geq p \geq n_1$ .

$$\begin{aligned} \therefore |a_1| |r_n| + |a_2| |r_{n-1}| + \dots + |a_p| |r_{n-p+1}| \\ < ( |a_1| + |a_2| + \dots + |a_p| ) \varepsilon \quad (\text{by 1}). \end{aligned}$$

$$= \overline{A_p} \varepsilon$$

$< \overline{a} \varepsilon$  (since  $(\overline{A_p})$  is a monotonic increasing sequence converging to  $\overline{a}$ )  
 ..... (5)

Also,  $|a_{p+1}| |r_{n-p}| + \dots + |a_n| |r_1| \leq (|a_{p+1}| + |a_{p+2}| + \dots + |a_n|) k$

(by 2)  
 $\leq (\overline{A_n} - \overline{A_p}) k$   
 $< \varepsilon k$  (by 3)

- $\therefore$  Using (5) and (6) in (4) we get
- $|R_n| < (\overline{a} + k) \varepsilon$  for all  $n \geq 2p$ .
- $\therefore (R_n) \rightarrow 0$ .
- $\therefore (c_n)$  converges to a b.
- $\therefore \sum C_n$  converges to a b.

**Power Series**

**Definition:**

A series of the form  $a_0 + a_1x + a_2x^2 + \dots + a_nx^n + \dots = \sum_{n=0}^{\infty} a_nx^n$  is called a power series in x. The number  $a_n$  are called the coefficients of the power series.

Example:

Consider the geometric series  $\sum_{n=0}^{\infty} x^n$ . Here  $a_n = 1$  for all n. This series converges absolutely if  $|x| < 1$ , diverges if  $x \geq 1$ , oscillates finitely if  $x = -1$  and oscillates infinitely if  $x < -1$

**Theorem: 5.10**

Let  $\sum a_nx^n$  be the given power series. Let  $\alpha = \lim sup |a_n|^{\frac{1}{n}}$  and let  $R = \frac{1}{\alpha}$ . Then  $\sum a_nx^n$  converges absolutely if  $|x| < R$ . If  $|x| > R$  the series is not convergent.

**Proof:**

Let  $c_n = a_nx^n$   
 $\therefore |c_n|^{\frac{1}{n}} = |a_n|^{\frac{1}{n}} |x|$   
 $\therefore \lim sup |c_n|^{\frac{1}{n}} = |x| \lim sup |a_n|^{\frac{1}{n}}$   
 $= |x| \frac{1}{R}$

Hence By Cauchy's root test the series converges if  $\frac{|x|}{R} < 1$ .

i.e) if  $|x| < R$

Now suppose  $|x| > R$ . Choose a real number  $\mu$  such that  $|x| > \mu > R$ .

$\therefore \frac{1}{\mu} < \frac{1}{R} = \lim sup |a_n|^{\frac{1}{n}}$

Hence by definition of upper limit, for infinite number of values of n we have

$|a_n|^{\frac{1}{n}} > \frac{1}{\mu} > \frac{1}{|x|}$

$\therefore |a_n x^n| > 1$  for finite number of values of  $n$ .  
Hence the series cannot converge.

**Definition:**

The number  $R = \frac{1}{\limsup |a_n|^{\frac{1}{n}}}$  given in the above theorem is called the radius of convergence of the power series  $\sum a_n x^n$

**Example:**

1. For the geometric series  $\sum x^n$ , the radius of convergence  $R=1$

2. Consider the exponential series  $1 + \frac{x}{1!} + \frac{x^2}{2!} + \dots + \frac{x^n}{n!} + \dots$

Here  $a_n = \frac{1}{n!}$

$$\left| \frac{a_n}{a_{n+1}} \right| = n + 1$$

$$\lim_{n \rightarrow \infty} \left| \frac{a_n}{a_{n+1}} \right| = \infty.$$

$\therefore R = \infty.$

Hence the series converges for all values of  $x$ .
